

To all our customers

Regarding the change of names mentioned in the document, such as Mitsubishi Electric and Mitsubishi XX, to Renesas Technology Corp.

The semiconductor operations of Hitachi and Mitsubishi Electric were transferred to Renesas Technology Corporation on April 1st 2003. These operations include microcomputer, logic, analog and discrete devices, and memory chips other than DRAMs (flash memory, SRAMs etc.) Accordingly, although Mitsubishi Electric, Mitsubishi Electric Corporation, Mitsubishi Semiconductors, and other Mitsubishi brand names are mentioned in the document, these names have in fact all been changed to Renesas Technology Corp. Thank you for your understanding. Except for our corporate trademark, logo and corporate statement, no changes whatsoever have been made to the contents of the document, and these changes do not constitute any alteration to the contents of the document itself.

Note : Mitsubishi Electric will continue the business operations of high frequency & optical devices and power devices.

— keep safety first in your circuit designs ! —

- Mitsubishi Electric Corporation puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage. Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of non-flammable material or (iii) prevention against any malfunction or mishap.

— Notes regarding these materials —

- These materials are intended as a reference to assist our customers in the selection of the Mitsubishi semiconductor product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Mitsubishi Electric Corporation or a third party.
- Mitsubishi Electric Corporation assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts or circuit application examples contained in these materials.
- All information contained in these materials, including product data, diagrams and charts, represent information on products at the time of publication of these materials, and are subject to change by Mitsubishi Electric Corporation without notice due to product improvements or other reasons. It is therefore recommended that customers contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor for the latest product information before purchasing a product listed herein.
- Mitsubishi Electric Corporation semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
- The prior written approval of Mitsubishi Electric Corporation is necessary to reprint or reproduce in whole or in part these materials.
- If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination. Any diversion or reexport contrary to the export control laws and regulations of JAPAN and/or the country of destination is prohibited.
- Please contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor for further details on these materials or the products contained therein.

Preface

This manual has been prepared to enable the users of the 7700 Family CMOS 16-bit microcomputers to better understand the instruction set and the features so that they can utilize the capabilities of the microcomputers to the fullest. This manual presents detailed descriptions of the instructions and addressing modes available for the 7700 Family microcomputers.

For the hardware descriptions of the 7700 Family microcomputers and descriptions of various development support tools (e.g., assembler, debugger, and so on.), please refer to the user's manuals and operating guidebooks for the respective hardware and software products.

DESCRIPTION

1.1 Description

EOL announced

DESCRIPTION

1.1 DESCRIPTION

1.1 Description

The 7700 Family software offer the following features.

1.1.1 7700 Series, 7770 Series, and 7790 Series software features

- m and x flags are used to select between word and byte operation enabling most instructions to be implemented with 1-byte operation code (reduces application ROM size)
- Powerful addressing modes, and fast and compact instruction set
- Direct page mapping function and memory oriented software system by direct paging
- The usual 64K bytes program memory boundary can be ignored for the practical purposes, and programs can be written to utilize the full 16M bytes of memory space
- For data memory linear as well as bank memory accessing are supported
- Bit manipulation instructions and bit test and branch instructions can be used for memory and I/O accessing of the entire 16M bytes space
- Block transfer instruction capable of handling blocks of up to 64K bytes each
- Decimal arithmetic instruction execution requiring no software compensation

1.1.2 7750 Series software features

The 7750 Series software is based on the Mitsubishi original 16-bit microcomputer 7700 Series and provides enhanced signed operation instructions. The signed operation enhancement is realized by additional instructions, instruction code and execution cycle of 7750 Series are completely compatible with those of conventional 7700 Series instructions.

In addition to the 7700 Series, 7770 Series, and 7790 Series software features, the 7750 Series software offer the following features.

- Upward compatibility for the 7700 Series
- Signed operation enhancements through signed divide/multiply, arithmetic shift right, and sign/zero extension instruction support

In this manual, 7700 Series software is described unless otherwise noted.

CHAPTER 2

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit (CPU)

EOL announced

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit (CPU)

2.1 Central processing unit (CPU)

The CPU of 7700 Series has the ten registers as shown in Figure 2.1.1. Each of these registers is described below.

2.1.1 Accumulator (Acc)

Accumulators A and B are available and each can be used as 8-bit or 16-bit register as necessary.

(1) Accumulator A (A)

Accumulator A is the main register of the microcomputer. Data operations such as calculations, data transfer, and input/output are executed mainly through accumulator A. It consists of 16 bits, and the low-order 8 bits can be also used separately. The data length flag (m) determines whether the register is used as a 16-bit register or as an 8-bit register. It is used as a 16-bit register when the flag m is "0", and as an 8-bit register when the flag m is "1". The flag m is a part of the processor status register (PS) which is described later. When an 8-bit register is selected, the low-order 8 bits of the accumulator A are used and the contents of the high-order 8 bits are unchanged.

(2) Accumulator B (B)

Accumulator B is a 16-bit register with the same function as accumulator A. The instructions of 7700 Series can use accumulator B instead of accumulator A, but the use of accumulator B requires more instruction bytes and execution cycles than accumulator A. Accumulator B is also controlled by the data length flag m just as in accumulator A.

2.1.2 Index register X (X)

Index register X consists of 16 bits and the low-order 8 bits can be also used separately. The index register length flag (x) determines whether the register is used as a 16-bit register or as an 8-bit register. It is used as a 16-bit register when the flag x is "0" and as an 8-bit register when the flag x is "1". The flag x is a part of the processor status register (PS) which is described later. When an 8-bit register is selected, the low-order 8 bits of the index register X are used and the contents of the high-order 8 bits are unchanged. In addressing mode in which the index register X is used as the index register, the contents of this register is added to obtain the real address.

When executing the block transfer instruction **MVP** or **MVN**, the contents of the index register X indicate the low-order 16 bits of the source data address. The third byte of the **MVP** or **MVN** instruction is the high-order 8 bits of the source data address.

2.1.3 Index register Y (Y)

Index register Y is a 16-bit register with the same function as index register X. Just as in index register X, the index register length flag (x) determines whether this register is used as a 16-bit register or as an 8-bit register.

When executing the block transfer instruction **MVP** or **MVN**, the contents of the index register Y indicate the low-order 16 bits of the destination data address. The second byte of the **MVP** or **MVN** instruction is the high-order 8 bits of the destination data address.

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit (CPU)

Fig. 2.1.1 CPU registers structure

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit (CPU)

2.1.4 Stack pointer (S)

Stack pointer S is a 16-bit register. It is used for a subroutine call or an interrupt. It is also used for addressing modes using the stack. The contents of the stack pointer S indicate the address (stack area) for storing registers during subroutine calls and interrupts.

When an interrupt request is accepted, the contents of the program bank register PG is stored at the address indicated by the contents of the stack pointer S, and the contents of the stack pointer S are decremented by 1. Then the contents of the program counter PC and the processor status register PS (PCH, PCL, PSH, PSL) are stored. The contents of the stack pointer S after accepting an interrupt request are equal to the contents of the stack pointer S before the accepting of the interrupt request decremented by 5.

Figure 2.1.2 shows the stored registers before an interrupt routine.

When returning to the original routine after processing the interrupt routine by executing the **RTI** instruction, the registers stored in the stack area are restored to the original registers in the reverse sequence and the contents of the stack pointer are returned to the numerical value before the accepting of interrupt request. The same operation is performed during a subroutine call, but the contents of the processor status register PS are not automatically stored. (The contents of the program bank register PG may not be stored. It depends on the addressing mode.)

The user is responsible for storing registers other than those described above with a program during interrupts or subroutine calls.

Additionally, the stack pointer S must be initialized at the beginning of the program because its contents are undefined at reset. The stack area changes when subroutines are nested or when multiple interrupt requests are accepted. Therefore, make sure necessary data in the internal RAM are not destroyed when nesting subroutines.

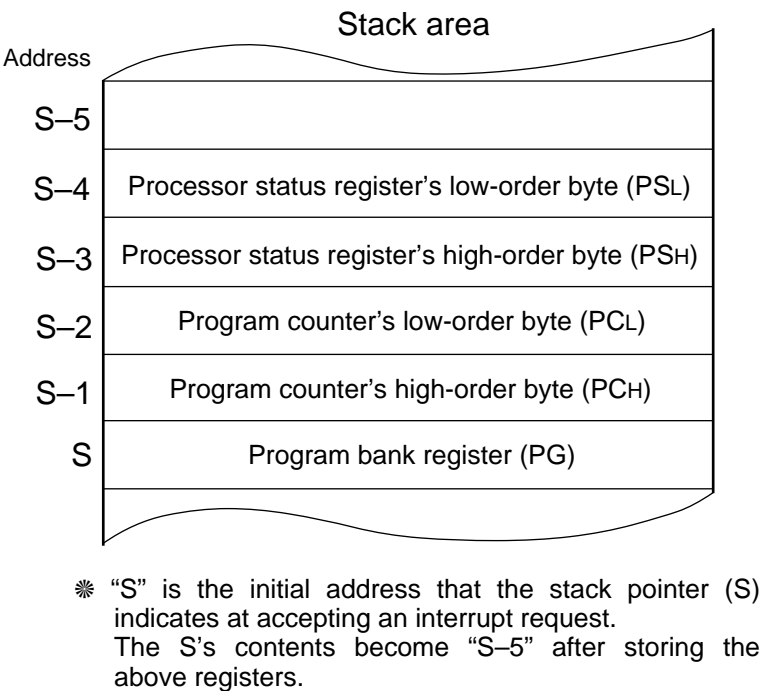

Fig. 2.1.2 Stored registers before an interrupt routine

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit (CPU)

2.1.5 Program counter (PC)

Program counter PC is a 16-bit counter that indicates the low-order 16 bits of the next program memory address (24 bits) to be executed. The contents of the high-order program counter (PCH) become “FF₁₆”, and the low-order program counter (PCL) become “FE₁₆” at reset. The contents of the program counter PC become the contents of the reset vector address (addresses FFFE₁₆, FFFF₁₆) after removing reset status. Figure 2.1.3 shows the program counter PC and the program bank register PG.

Fig. 2.1.3 Program counter PC and program bank register PG

2.1.6 Program bank register (PG)

Program bank register PG is an 8-bit register that indicates the high-order 8 bits (referred to as bank) of the next program memory address (24 bits) to be executed.

When a carry occurs after adding the contents of the program counter PC and other factors, the contents of the program bank register PG are automatically incremented by 1. When a borrow occurs after subtracting the contents of the program counter PC, the contents of the program bank register PG are automatically decremented by 1. Accordingly, there is no need to consider bank boundaries, usually.

This register is cleared to “00₁₆” at reset.

In single-chip mode, keep the program bank register PG “00₁₆” because the access within bank 0₁₆ is only allowed. Be sure that prevent the program bank register PG from being set to a value other than “00₁₆” by executing the instructions of branch and so on.

This register is cleared to “00₁₆” at reset.

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit (CPU)

2.1.7 Data bank register (DT)

Data bank register DT is an 8-bit register. With some addressing modes using the data bank register DT, the contents of this register are used as the high-order 8 bits (bank) of a 24-bit address.

Use the **LDT** instruction to set the value in this register.

Set the only "00₁₆" in single-chip mode because the access within bank 0₁₆ is only allowed.

This register is cleared to "00₁₆" at reset.

2.1.8 Direct page register (DPR)

Direct page register DPR is a 16-bit register. The contents of this register indicate the direct page area which is allocated in bank 0₁₆ or in the area across banks 0₁₆ and 1₁₆. This area can be accessed with 2 bytes* by using the direct page addressing mode.

The contents of the DPR are the base address (the lowest address) of the direct page area which extends to 256 bytes above this address. The DPR can contain a value from 0000₁₆ to FFFF₁₆. However, set a value from 0000₁₆ to FF00₁₆ in single-chip mode because the access within bank 0₁₆ is only allowed.

If it contains a value equal to or more than "FF01₁₆", the direct page area spans the area across banks 0₁₆ and 1₁₆. If the low-order 8 bits of the DPR is "00₁₆", the number of cycles required to generate an address is smaller by 1 cycle than the number if its contents are not "00₁₆". Accordingly, the low-order 8 bits of the DPR should usually be set to "00₁₆".

This register is cleared to "0000₁₆" at reset. Figure 2.1.4 shows a setting example of the direct page with the direct page register (DPR).

* With 3 bytes for **DIV** and **MPY** instructions, and 1 byte is added for all instructions when using accumulator B.

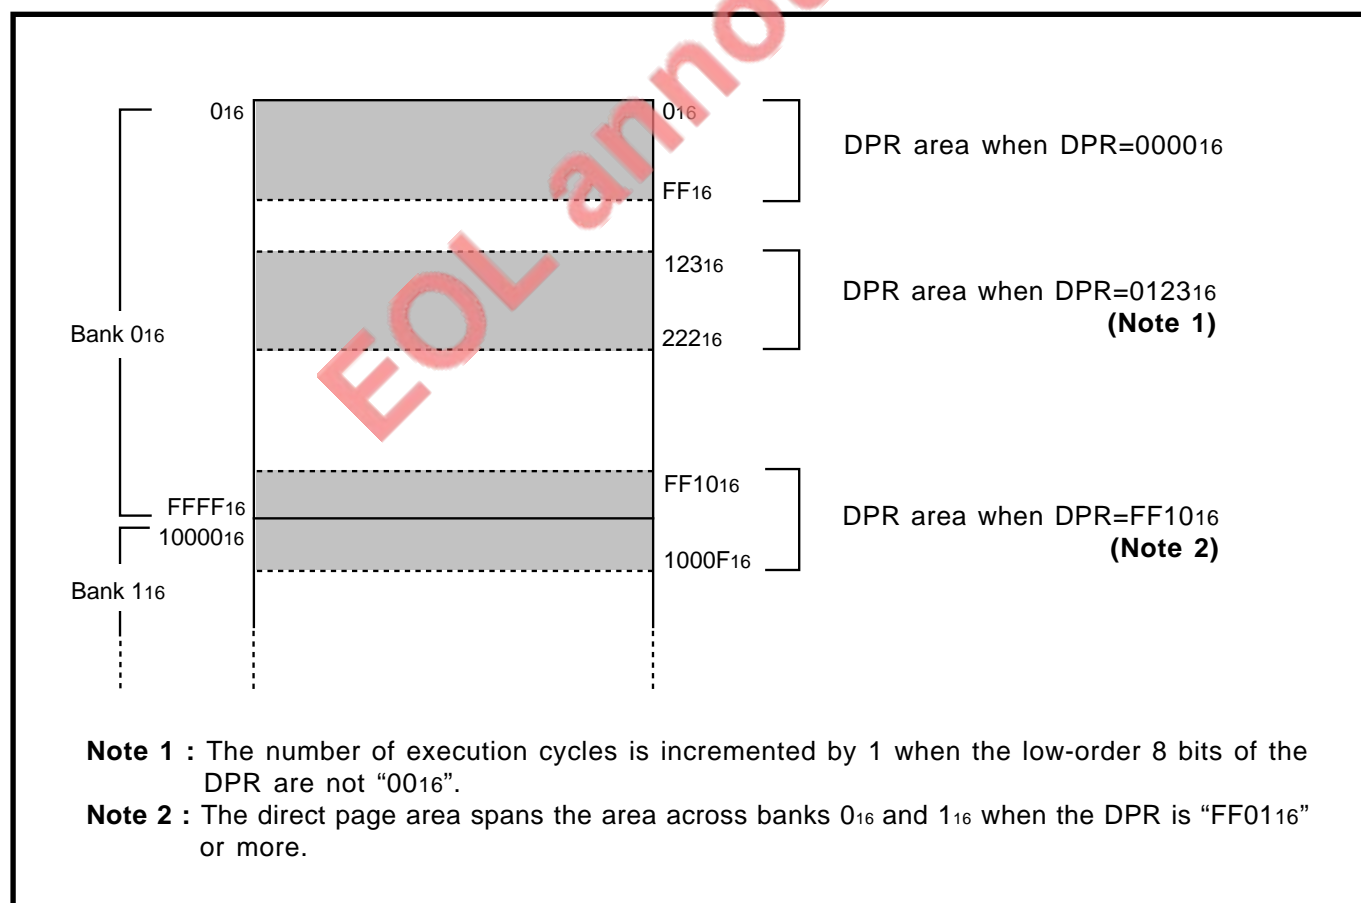

Fig. 2.1.4 Setting example of direct page with direct page register (DPR)

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit (CPU)

2.1.9 Processor status register (PS)

Processor status register is an 11-bit register. It consists of the flags to indicate the result of operation and the processor interrupt priority level. The flags C, Z, V, and N are tested by branch instructions.

Figure 2.1.5 shows the structure of the processor status register.

The details of the processor status register flags are described below.

b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
0	0	0	0	0		IPL		N	V	m	x	D	I	Z	C

Note: Bits 11 to 15 are always “0” when the contents of the processor status register are read.

Fig. 2.1.5 Processor status register structure

(1) Carry flag (C)

The carry flag is assigned to bit 0 of the processor status register. It contains the carry or borrow bit from the arithmetic and logic unit (ALU) after an arithmetic operation. This flag is also affected by shift and rotate instructions. This flag can be set with the **SEC** or **SEP** instruction and cleared with the **CLC** or **CLP** instruction.

(2) Zero flag (Z)

The zero flag is assigned to bit 1 of the processor status register. It is set to “1” when the result of an arithmetic operation or data transfer is zero, and cleared to “0” when otherwise. This flag can be set with the **SEP** instruction and cleared with the **CLP** instruction.

Note: This flag has no meaning in decimal mode addition (the **ADC** instruction).

(3) Interrupt disable flag (I)

The interrupt disable flag is assigned to bit 2 of the processor status register. It disables all maskable interrupts (interrupts other than watchdog timer, the **BRK** instruction, and zero division). Interrupts are disabled when this flag is “1”. When an interrupt request is accepted, this flag is automatically set to “1” to avoid multiple interrupts. This flag can be set with the **SEI** or **SEP** instruction and cleared with the **CLI** or **CLP** instruction. This flag is set to “1” at reset.

(4) Decimal mode flag (D)

The decimal mode flag is assigned to bit 3 of the processor status register. It determines whether addition and subtraction are performed in binary or decimal. Binary arithmetic is performed when this flag is “0”. When it is “1”, decimal arithmetic is performed with each word treated as two or four digits decimal (determined by the data length flag m). Decimal adjust is performed automatically. Decimal operation is possible only with the **ADC** and **SBC** instructions. This flag can be set with the **SEP** instruction and cleared with the **CLP** instruction. This flag is cleared to “0” at reset.

(5) Index register length flag (x)

The index register length flag is assigned to bit 4 of the processor status register. It determines whether the index register X and index register Y are used as a 16-bit register or an 8-bit register. The register is used as a 16-bit register when this flag x is “0”, and as an 8-bit register when it is “1”. This flag can be set with the **SEP** instruction and cleared with the **CLP** instruction. This flag is cleared to “0” at reset.

✱ When transferring between different bit lengths, the data is transferred with the length of the destination register, but except for the **TXA**, **TYA**, **TXB**, and **TYB** instructions.

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit (CPU)

(6) Data length flag (m)

The data length flag is assigned to bit 5 of the processor status register. It determines whether to treat data as a 16-bit unit or as an 8-bit unit. A data is treated as a 16-bit unit when this flag m is "0", and as an 8-bit unit when it is "1".

This flag can be set with the **SEM** or **SEP** instruction and cleared with the **CLM** or **CLP** instruction. This flag is cleared to "0" at reset.

✱ When transferring between different bit lengths, the data is transferred with the length of the destination register, but except for the **TXA**, **TYA**, **TXB**, and **TYB** instructions.

(7) Overflow flag (V)

The overflow flag is assigned to bit 6 of the processor status register. It is used when adding or subtracting a word as signed binary. In case the data length flag m is "0", the overflow flag is set to "1" when the result of addition or subtraction is outside the range between -32768 and +32767, and cleared to "0" in all other cases. In case the data length flag m is "1", the overflow flag is set to "1" when the result of addition or subtraction is outside the range between -128 and +127, and cleared to "0" in all other cases. The overflow flag can be set with the **SEP** instruction and cleared with the **CLV** or **CLP** instructions.

Note : This flag has no meaning in decimal mode.

(8) Negative flag (N)

The negative flag is assigned to bit 7 of the processor status register. It is set to "1" when the result of arithmetic operation or data transfer is negative (data bit 15 is "1" when the data length flag m is "0", or data bit 7 is "1" when the data length flag m is "1"). It is cleared to "0" in all other cases. This flag can be set with the **SEP** instruction and cleared with the **CLP** instruction.

Note : This flag has no meaning in decimal mode.

(9) Processor interrupt priority level (IPL)

The processor interrupt priority level (IPL) is assigned to bits 8, 9, and 10 of the processor status register. These three bits determine the priority level of processor interrupts from level 0 to level 7. The interrupt is enabled when the interrupt priority level of a required interrupt (set with the interrupt control register) is higher than IPL. When an interrupt request is accepted, the IPL is stored in the stack and IPL is replaced by the interrupt priority level of the accepted interrupt request. This simplifies control of multiple interrupts.

There are no instructions to directly set or clear the IPL. It can be changed by placing the new IPL on the stack and updating the processor status register with the **PUL** or **PLP** instruction.

The contents of the IPL are cleared to "0002" at reset.

CHAPTER 3

ADDRESSING MODES

3.1 Addressing modes

3.2 Explanation of addressing
modes

ADDRESSING MODES

3.1 Addressing Modes, 3.2 Explanation of Addressing Modes

3.1 Addressing Modes

When executing an instruction, the address of the memory location from which the data required for arithmetic operation is to be retrieved or to which the result of arithmetic operation is to be stored must be specified in advance. Address specification is also necessary when the control is to jump to a certain memory address during program execution. Addressing refers to the method of specifying the memory address.

The 7700 Series microcomputers support 28 different addressing modes, offering extremely versatile and powerful memory accessing capability.

3.2 Explanation of Addressing Modes

Each of the 28 addressing modes is explained on the pages indicated below:

Implied addressing mode	3-3
Immediate addressing mode	3-4
Accumulator addressing mode	3-6
Direct addressing mode	3-7
Direct bit addressing mode	3-9
Direct indexed X addressing mode	3-11
Direct indexed Y addressing mode	3-14
Direct indirect addressing mode	3-15
Direct indexed X indirect addressing mode	3-17
Direct indirect indexed Y addressing mode	3-20
Direct indirect long addressing mode	3-23
Direct indirect long indexed Y addressing mode	3-25
Absolute addressing mode	3-28
Absolute bit addressing mode	3-31
Absolute indexed X addressing mode	3-33
Absolute indexed Y addressing mode	3-36
Absolute long addressing mode	3-39
Absolute long indexed X addressing mode	3-41
Absolute indirect addressing mode	3-43
Absolute indirect long addressing mode	3-44
Absolute indexed X indirect addressing mode	3-45
Stack addressing mode	3-46
Relative addressing mode	3-49
Direct bit relative addressing mode	3-50
Absolute bit relative addressing mode	3-52
Stack pointer relative addressing mode	3-54
Stack pointer relative indirect indexed Y addressing mode	3-55
Block transfer addressing mode	3-58

Note. On the pages below, the instructions with the mark “ * ” can be used in the 7750 Series only.

Implied

Mode : Implied addressing mode

Function : The single-instruction inherently address an internal register.

Instruction : BRK, CLC, CLI, CLM, CLV, DEX, DEY, INX, INY, NOP, RTI, RTL,
RTS, SEC, SEI, SEM, STP, TAD, TAS, TAX, TAY, TBD, TBS, TBX,
TBY, TDA, TDB, TSA, TSB, TSX, TXA, TXB, TXS, TXY, TYA, TYB,
TYX, WIT, XAB

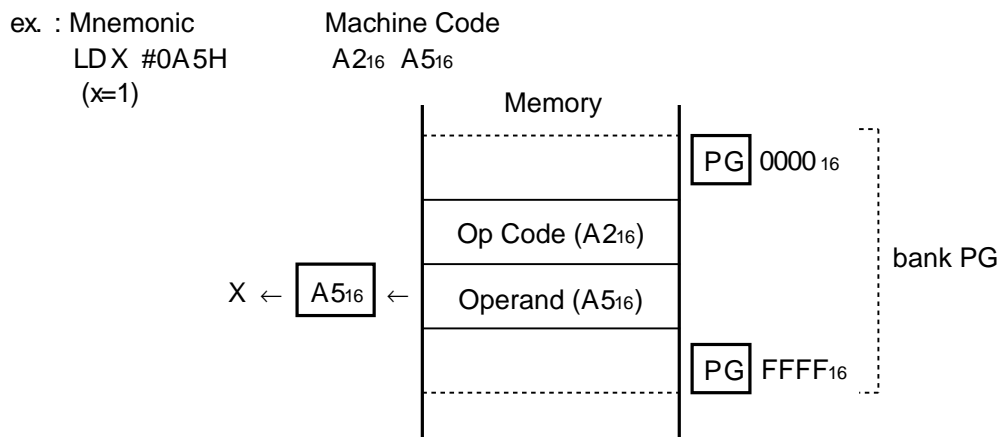

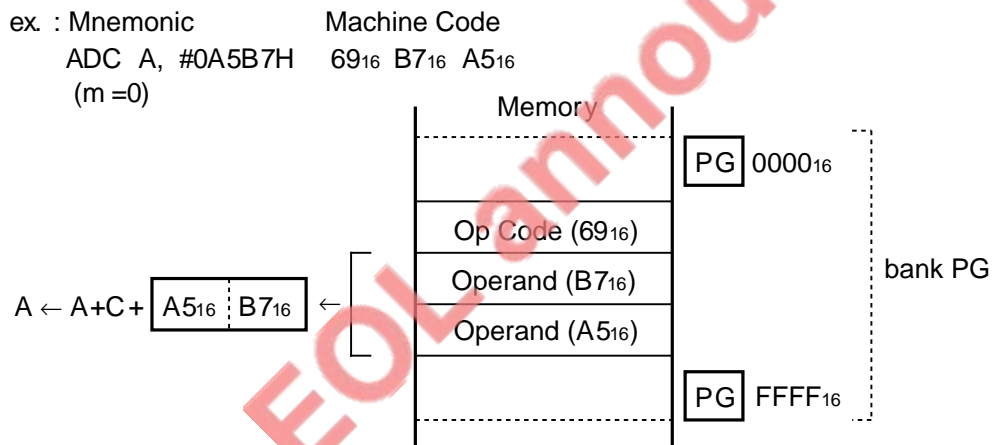

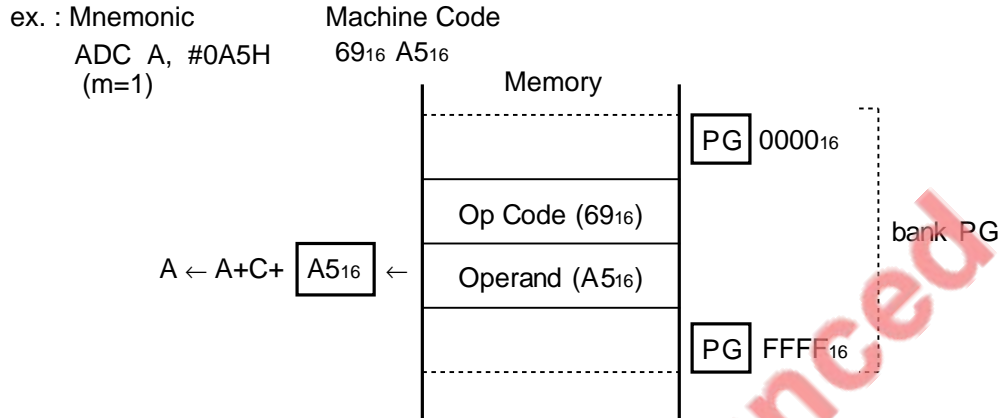

Immediate

Mode : Immediate addressing mode

Function : A portion of the instruction is the actual data. Such instruction code may cross over the bank boundary.

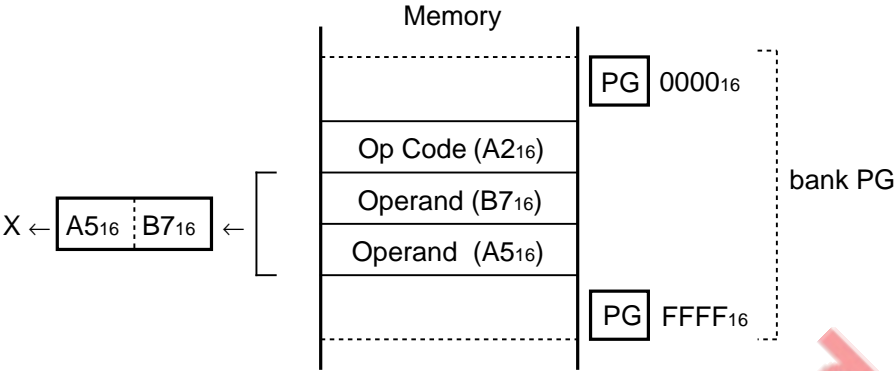

Instruction : ADC, AND, CLP, CMP, CPX, CPY, DIV, DIVS*, EOR, LDA, LDT, LDX,
LDY, MPY, MPYS*, ORA, RLA, SBC, SEP

Immediate

ex. : Mnemonic
LDX #0A5B7H
(x=0)

Machine Code
A2₁₆ B7₁₆ A5₁₆

EOL announced

Accumulator

Mode : Accumulator addressing mode

Function : The contents of accumulator are the actual data.

Instruction : ASL, ASR*, DEC, EXTS*, EXTZ*, INC, LSR, ROL, ROR

ex. : Mnemonic	Machine Code
ROL A (m=1)	2A ₁₆

ex. : Mnemonic	Machine Code
ROL A (m=0)	2A ₁₆

Direct

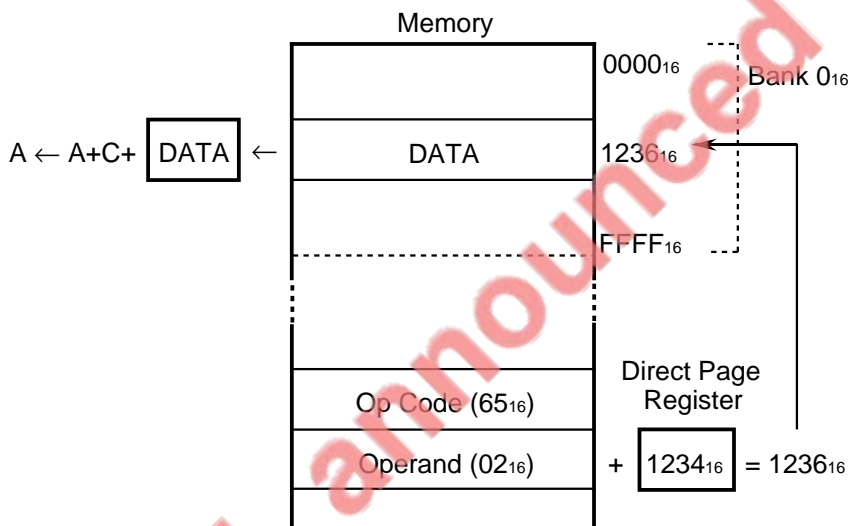

Mode : Direct addressing mode

Function : The contents of the bank 0₁₆ memory location specified by the result of adding the second byte of the instruction to the contents of the direct page register become the actual data. If, however, addition of the instruction's second byte to the direct page register's contents result in a value that exceeds the bank 0₁₆ range, the specified location will be in bank 1₁₆.

Instruction : ADC, AND, ASL, ASR*, CMP, CPX, CPY, DEC, DIV, DIVS*, EOR, INC, LDA, LDM, LDX, LDY, LSR, MPY, MPYS*, ORA, ROL, ROR, SBC, STA, STX, STY

(m=0, x=0)

Machine Code
 61_{16} $1E_{16}$

Direct Indirect Indexed Y

Mode : Direct indirect indexed Y addressing mode

Function : The value obtained by adding the instruction's second byte and the contents of the direct page register specifies 2 adjacent bytes in memory bank 0₁₆.
The value obtained by adding the contents of these bytes and the contents of the index register Y specifies address of the actual data in memory bank DT (DT is contents of data bank register).
If, however, the value obtained by adding the contents of the instruction's second byte and the direct page register exceeds the bank 0₁₆ range, the specified location will be in bank 1₁₆. Also, if addition of the contents of memory and index register Y generate a carry, the bank number will be 1 larger than the contents of the data bank register.

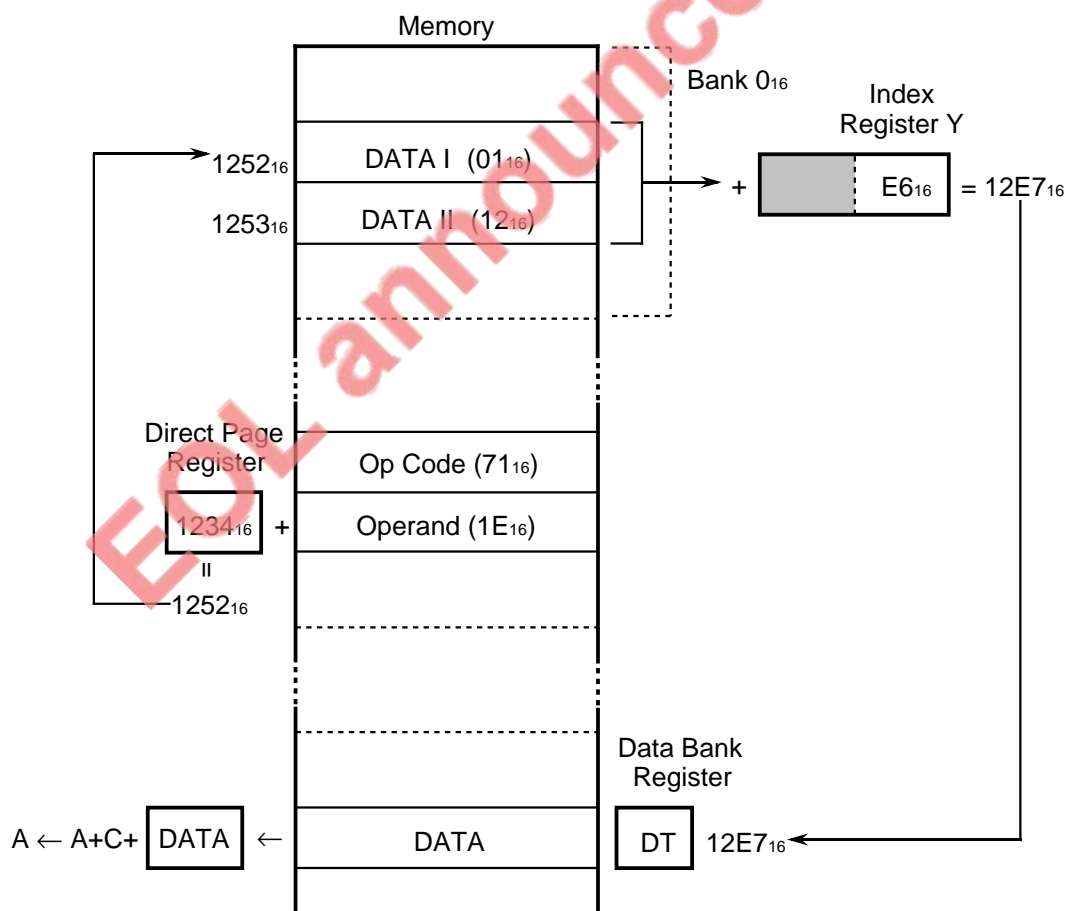

Instruction : ADC, AND, CMP, DIV, DIVS*, EOR, LDA, MPY, MPYS*, ORA, SBC, STA

ex. : Mnemonic

ADC A, (1EH), Y
(m=1, x=1)

Machine Code

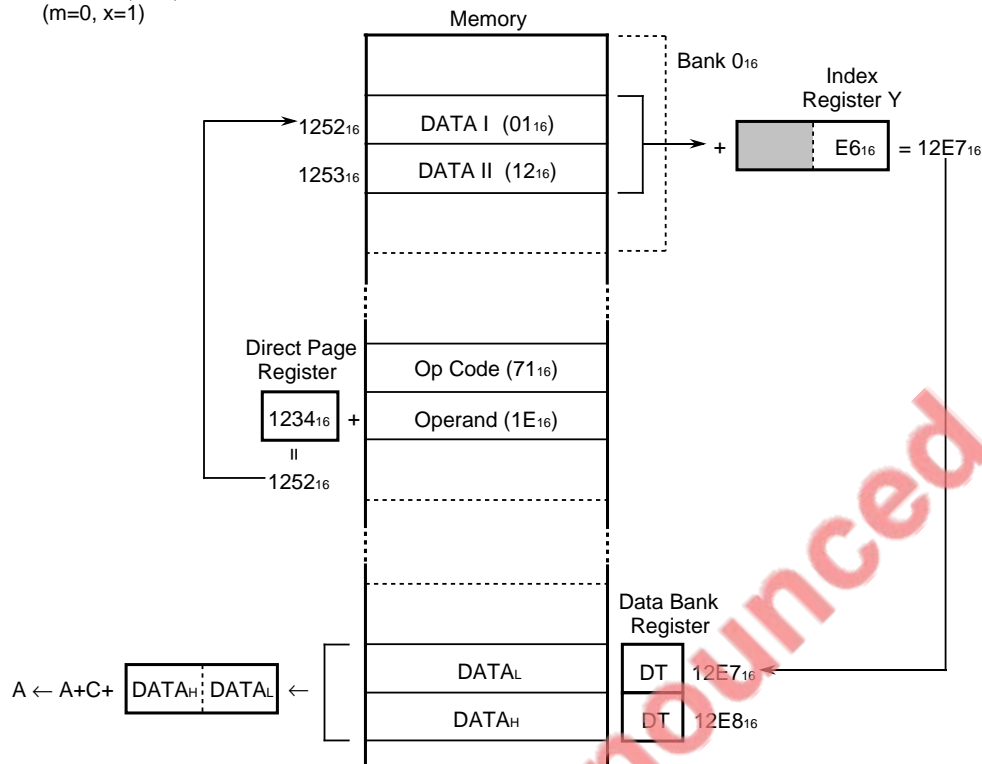

71₁₆ 1E₁₆

Direct Indirect Indexed Y

Machine Code

ADC A, (1EH), Y
(m=0, x=0)

71₁₆ 1E₁₆

Direct Indirect Long

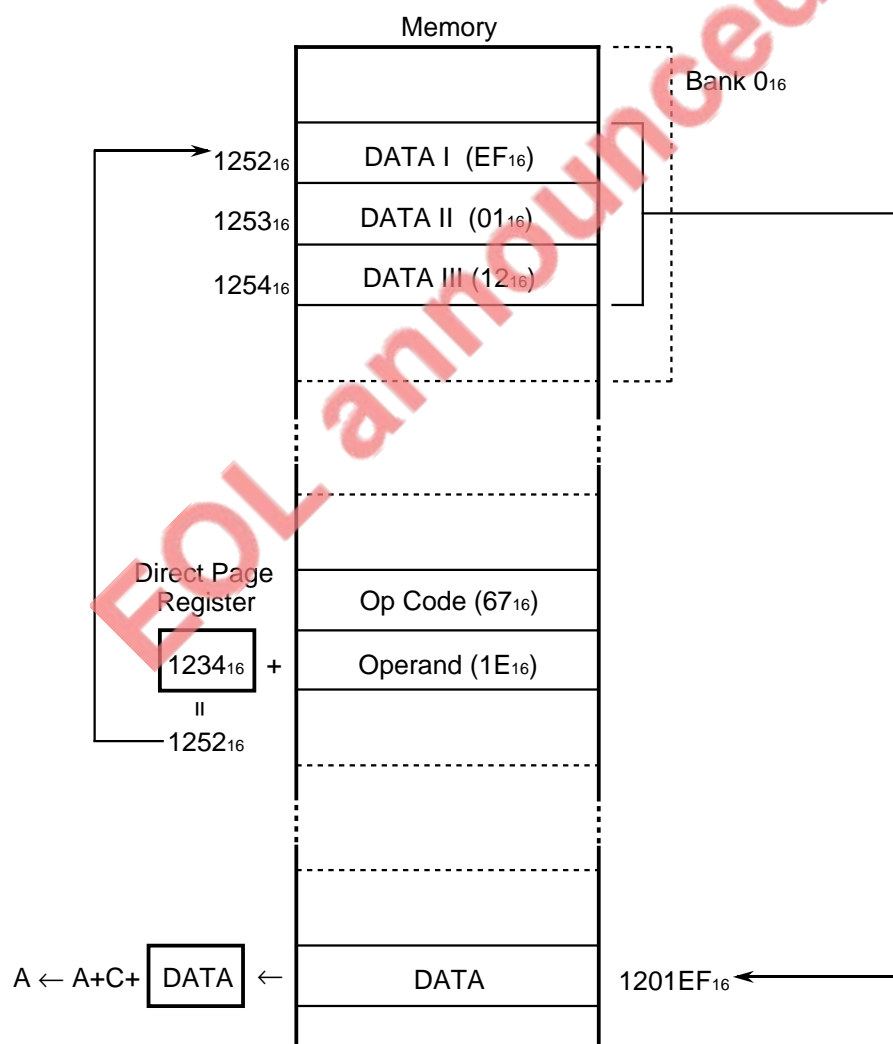

Mode : Direct indirect long addressing mode

Function : The value obtained by adding the instruction's second byte and the contents of the direct page register specifies 3 adjacent bytes in memory bank 0₁₆, and the contents of these bytes specify the address of the memory location that contains the actual data. If, however, the value obtained by adding the contents of the instruction's second byte and the direct page register exceeds the bank 0₁₆ range, the specified location will be in bank 1₁₆. The 3 adjacent bytes memory location may be spread over two different banks.

Instruction : ADC, AND, CMP, DIV, DIVS*, EOR, LDA, MPY, MPYS*,ORA, SBC, STA

ex. : Mnemonic
ADCL A, (1EH)
(m=1)

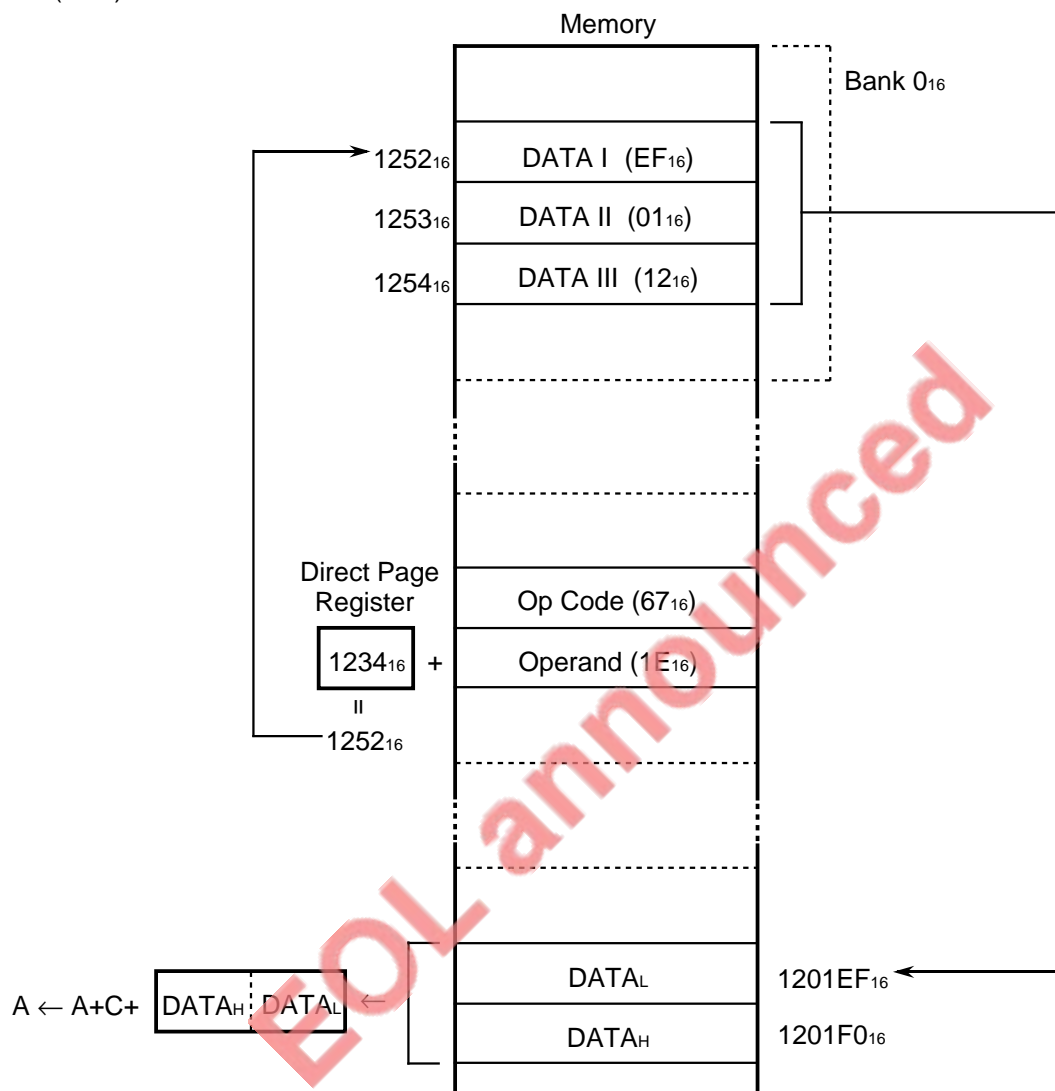

Machine Code
67₁₆ 1E₁₆

Direct Indirect Long

ex. : Mnemonic

(m=0, x=0)

Machine Code

77₁₆ 1E₁₆

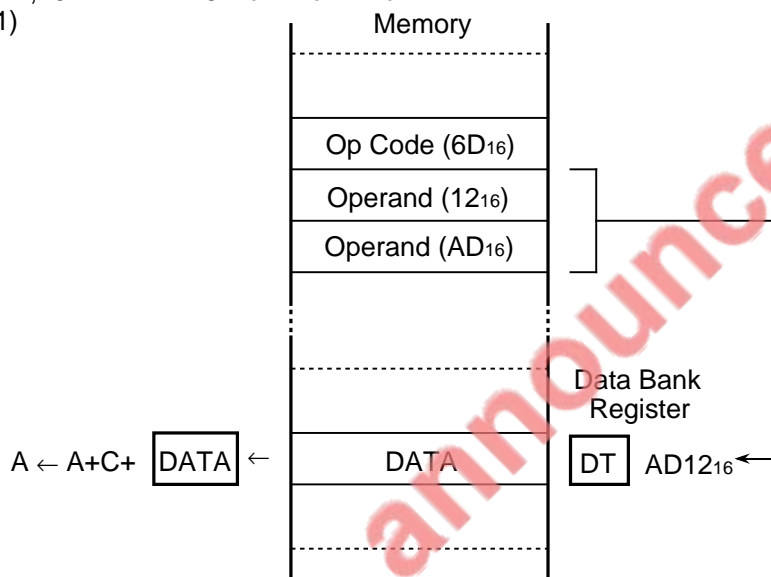

Absolute

Mode : Absolute addressing mode

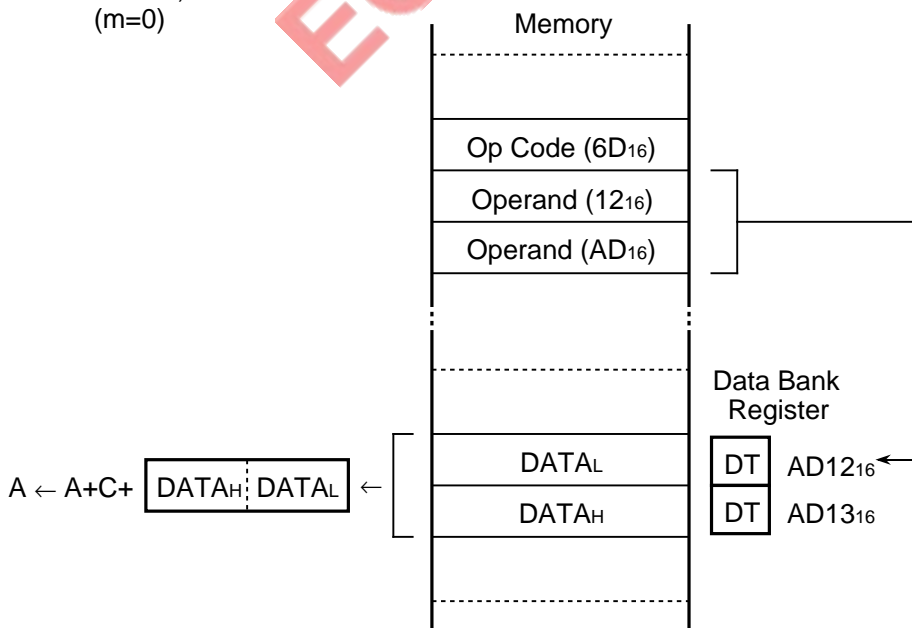

Function : The contents of the memory locations specified by the instruction's second and third bytes and the contents of the data bank register are the actual data. Note that, in the cases of the JMP and JSR instructions, the instructions' second and third byte contents are transferred to the program counter.

Instruction : ADC, AND, ASL, ASR*, CMP, CPX, CPY, DEC, DIV, DIVS*, EOR, INC, JMP, JSR, LDA, LDM, LDX, LDY, LSR, MPY, MPYS*, ORA, ROL, ROR, SBC, STA, STX, STY

ex.: Mnemonic Machine Code
 ADC A, 0AD12H 6D₁₆ 12₁₆ AD₁₆
 (m=1)

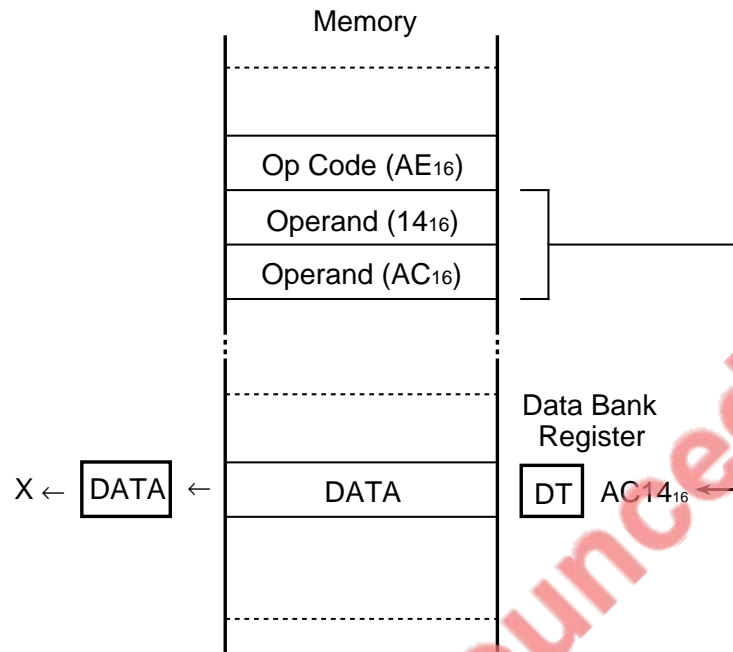

ex. : Mnemonic Machine Code
 ADC A, 0AD12H 6D₁₆ 12₁₆ AD₁₆
 (m=0)

Absolute

(Note) The branch destination bank must be considered carefully when a JMP or a JSR instruction is located near a bank boundary.
→Refer the description of a JMP instruction (Page 4-50).
Refer the description of a JSR instruction (Page 4-51).

Absolute Bit

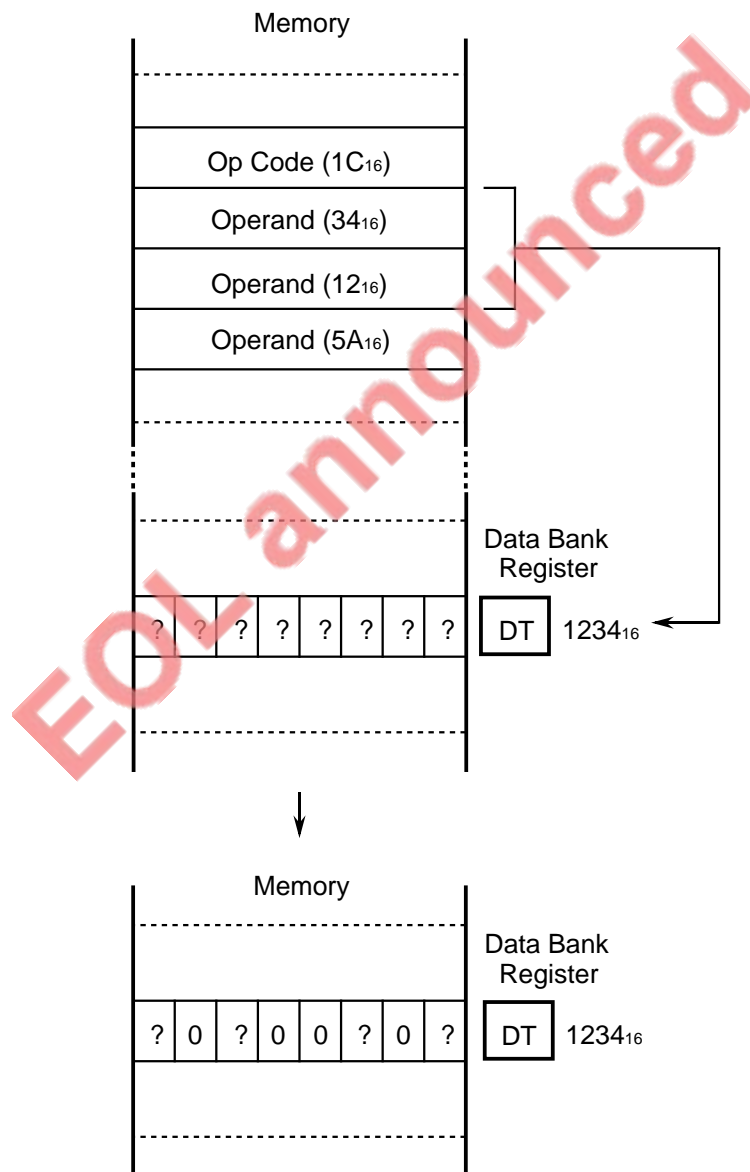

Mode : Absolute bit addressing mode

Function : The contents of the instruction's second and third bytes and the contents of the data bank register specify the memory locations, and data for multiple bit positions in the memory locations are specified by a bit pattern specified in the instruction's fourth and fifth bytes (the fourth byte only if the m flag is set to 1).

Instruction : CLB, SEB

ex. : Mnemonic
CLB #5AH, 1234H
(m=1)

Machine Code
1C₁₆ 34₁₆ 12₁₆ 5A₁₆

Machine Code

1C₁₆ 34₁₆ 12₁₆ A5₁₆ 5A₁₆

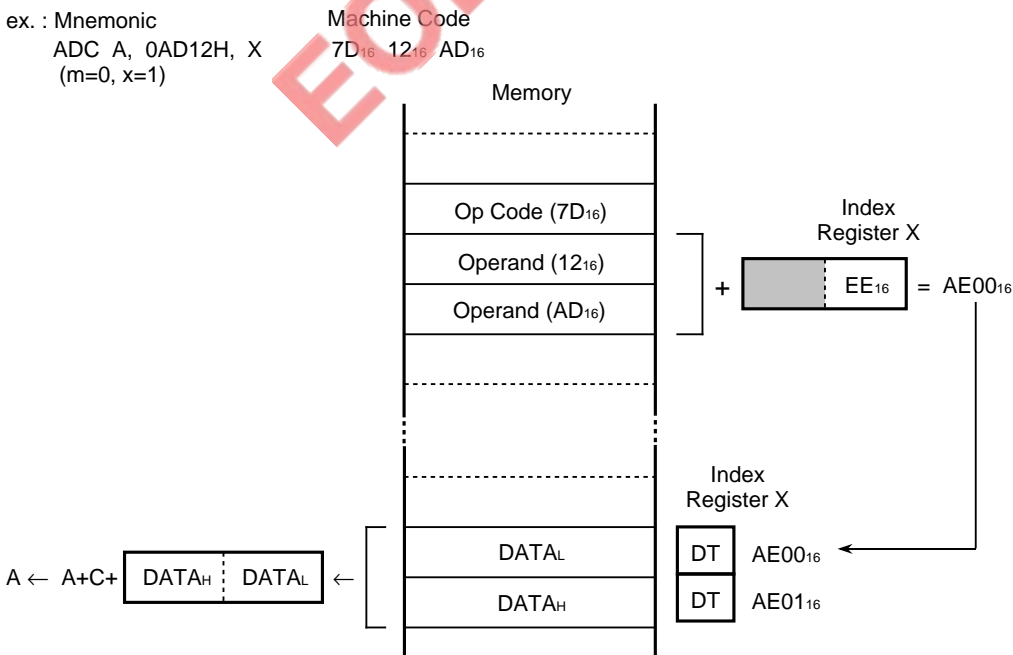

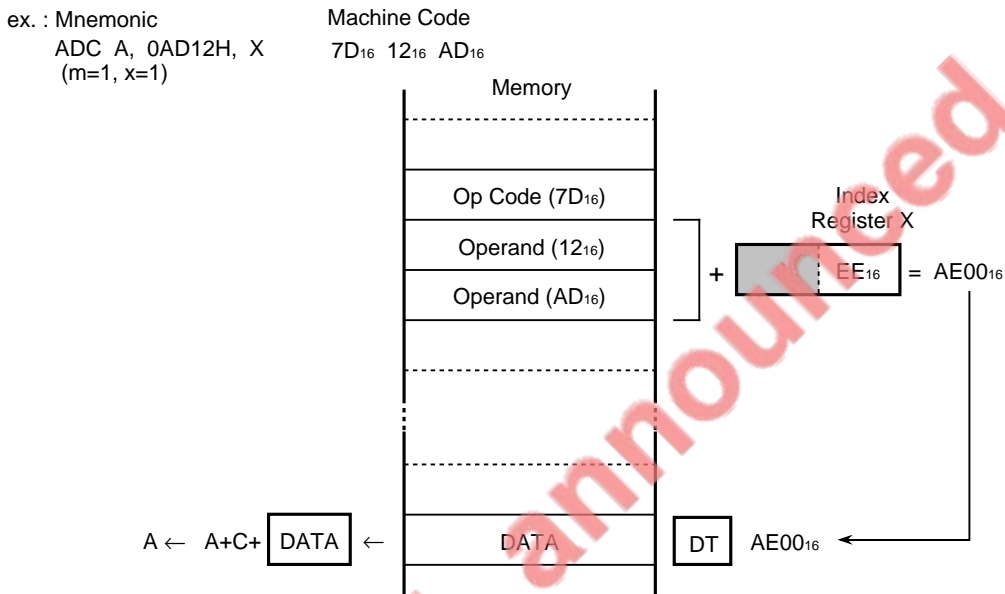

Absolute Indexed X

Mode : Absolute indexed X addressing mode

Function : The contents of the memory locations specified by a value resulting from addition of a 16-bit numeric value expressed by the instruction's second and third bytes with the contents of the index register X and the contents of the data bank register are the actual data. If, however, addition of the numeric value expressed by the instruction's second and third bytes with the contents of the index register X generates a carry, the bank number will be 1 larger than the contents of the data bank register.

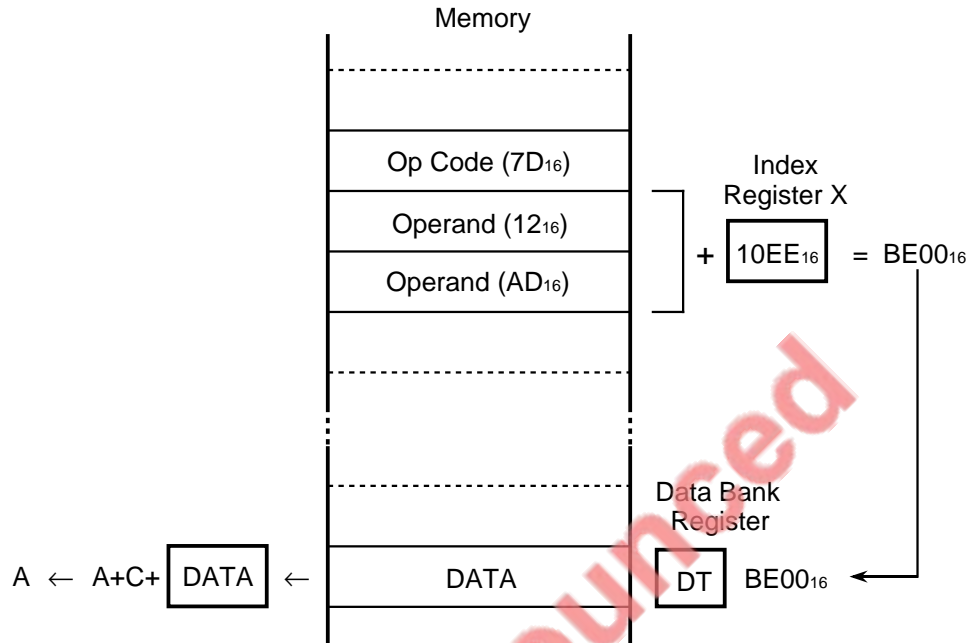

Instruction : ADC, AND, ASL, ASR*, CMP, DEC, DIV, DIVS*, EOR, INC, LDA, LDM, LDY, LSR, MPY, MPYS*, ORA, ROL, ROR, SBC, STA

Absolute Indexed X

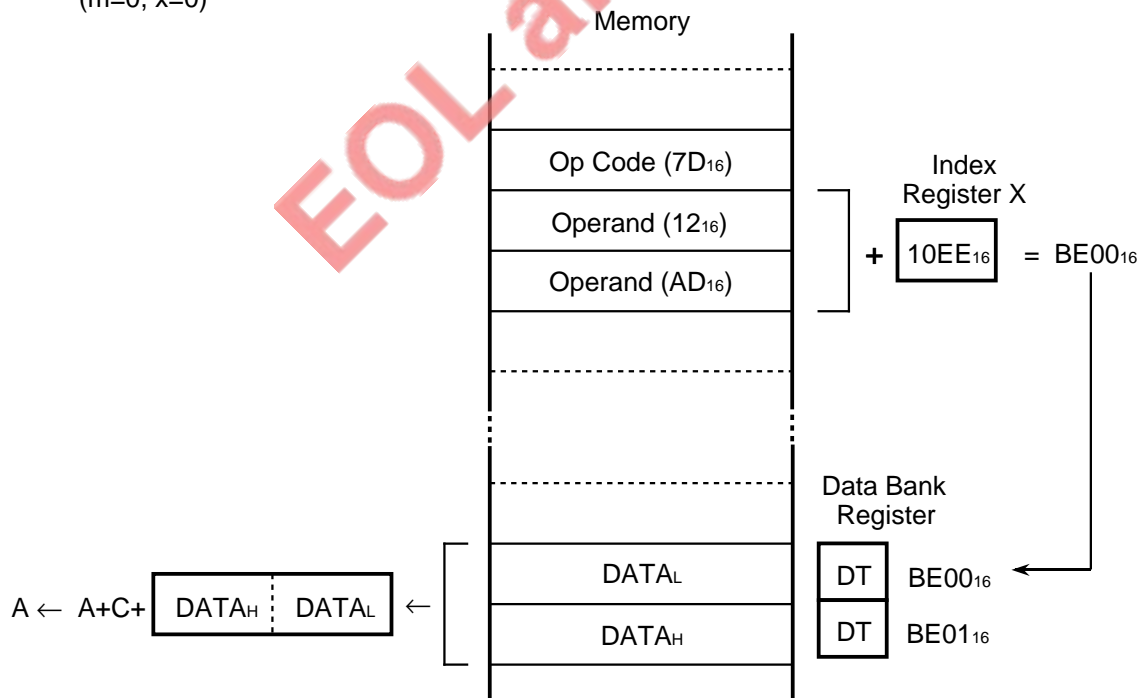

ex. : Mnemonic

Absolute Long

ex. : Mnemonic
JMPL 123456H

Machine Code
 $5C_{16}$ 56_{16} 34_{16} 12_{16}

Absolute Long Indexed X

- Mode** : Absolute long indexed X addressing mode
- Function** : The contents of the memory location specified by adding the numeric value expressed by the instruction's second, third and fourth bytes with the contents of the index register X are the actual data.
- Instruction** : ADC, AND, CMP, DIV, DIVS*, EOR, LDA, MPY, MPYS*,ORA, SBC, STA

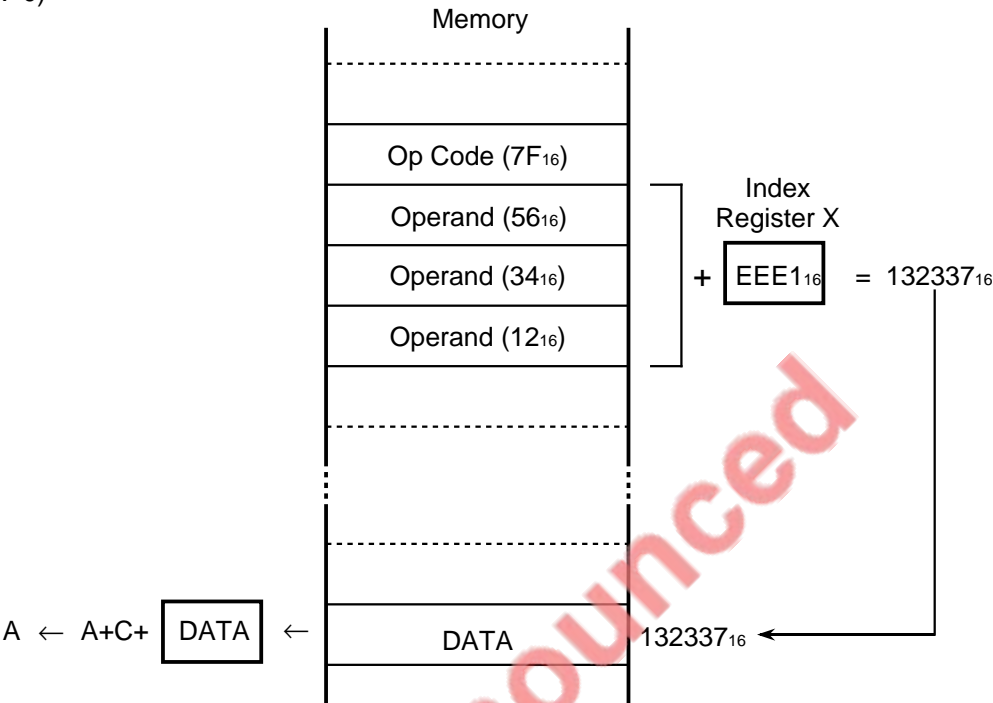

Absolute Long Indexed X

ex. : Mnemonic

ADC A, 123456H, X
(m=1, x=0)

Machine Code

7F₁₆ 56₁₆ 34₁₆ 12₁₆

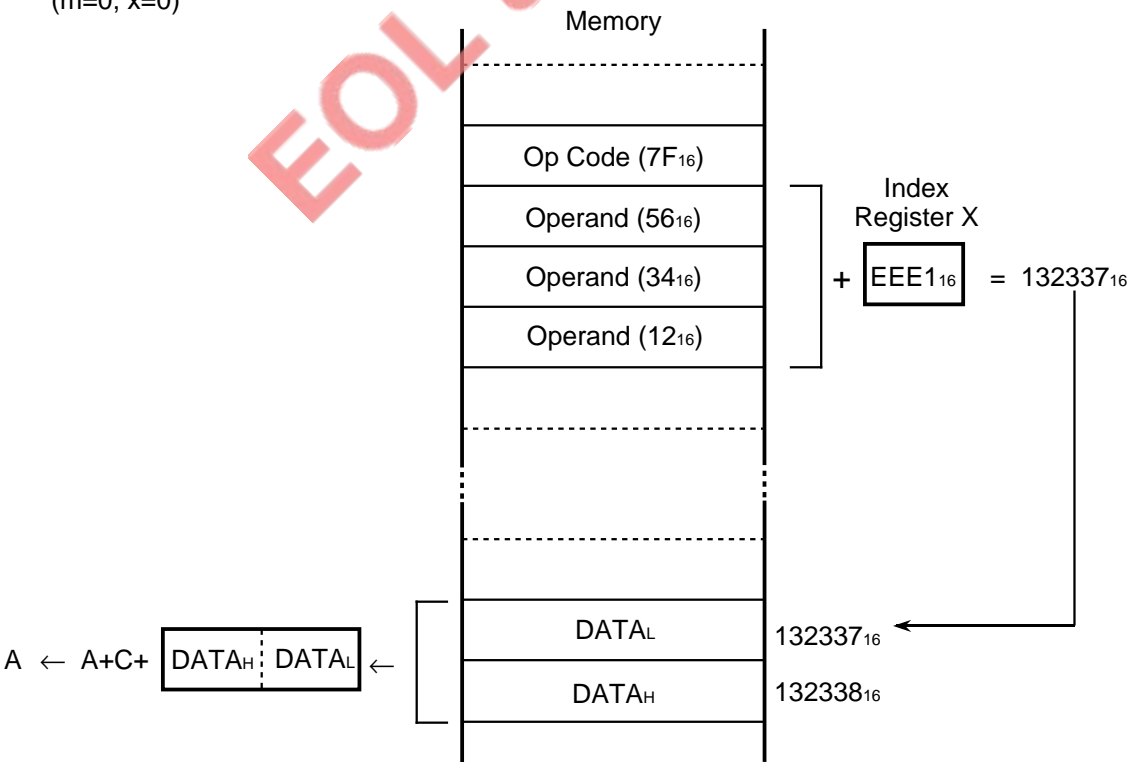

ex. : Mnemonic

ADC A, 123456H, X
(m=0, x=0)

Machine Code

7F₁₆ 56₁₆ 34₁₆ 12₁₆

Absolute Indirect

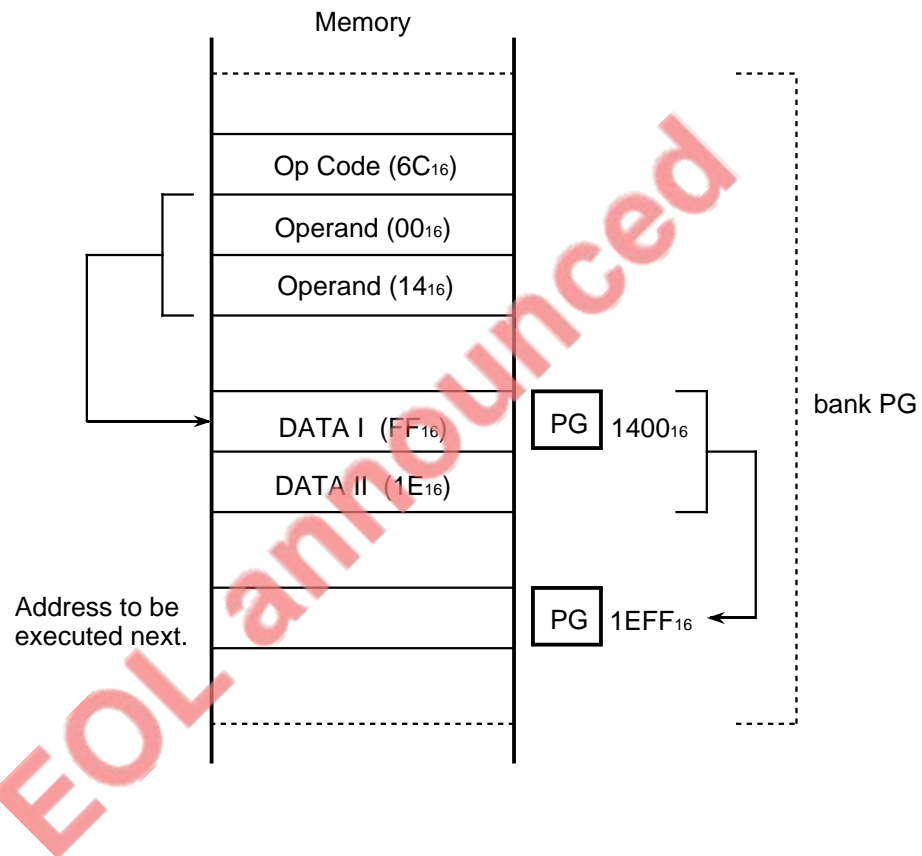

Mode : Absolute indirect addressing mode

Function : The instruction's second and third bytes specify 2 adjacent bytes in memory, and the contents of these bytes specify the address within the same program bank to which a jump is to be made.

Instruction : JMP

ex. : Mnemonic
JMP (1400H)

Machine Code
6C₁₆ 00₁₆ 14₁₆

(Note) The branch destination bank must be considered carefully when a JMP instruction is located near a bank boundary.
→Refer the description of a JMP instruction (Page 4-50).

Absolute Indirect Long

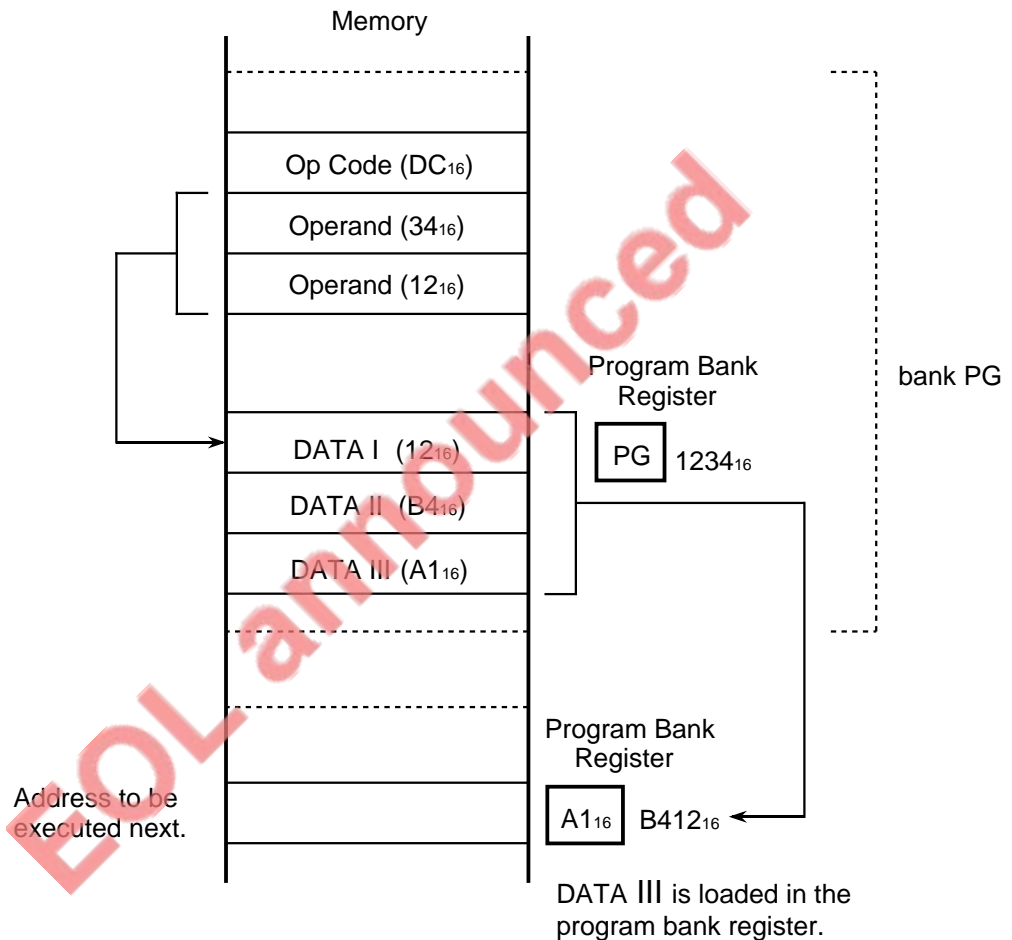

Mode : Absolute indirect long addressing mode

Function : The instruction's second and third bytes specify 3 adjacent bytes in memory, and the contents of these bytes specify the address to which a jump is to be made.

Instruction : JMP

ex. : Mnemonic
JMPL (1234H)

Machine Code
DC₁₆ 34₁₆ 12₁₆

(Note) The branch destination bank must be considered carefully when a JMP instruction is located near a bank boundary.
→Refer the description of a JMP instruction (Page 4-50).

Absolute Indexed X Indirect

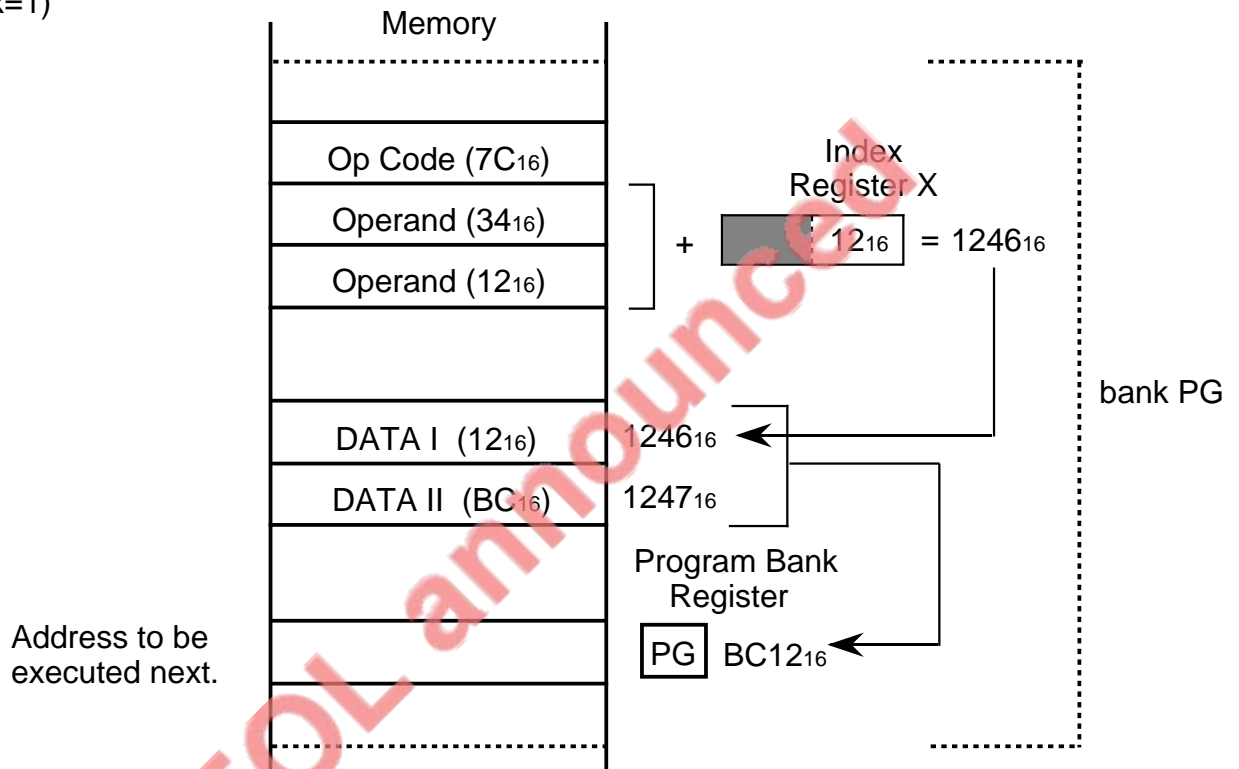

Mode : Absolute indexed X indirect addressing mode

Function : The value obtained by adding the instruction's second and third bytes and the contents of the index register X specifies 2 adjacent bytes in memory, and the contents of these bytes specify the address to which a jump is to be made.

Instruction : JMP, JSR

ex. : Mnemonic
JMP (1234H, X)
(x=1)

Machine Code
7C₁₆ 34₁₆ 12₁₆

(Note) The branch destination bank must be considered carefully when a JMP or a JSR instruction is located near a boundary.
→Refer the description of a JMP instruction (Page 4-50).
Refer the description of a JSR instruction (Page 4-51).

Stack

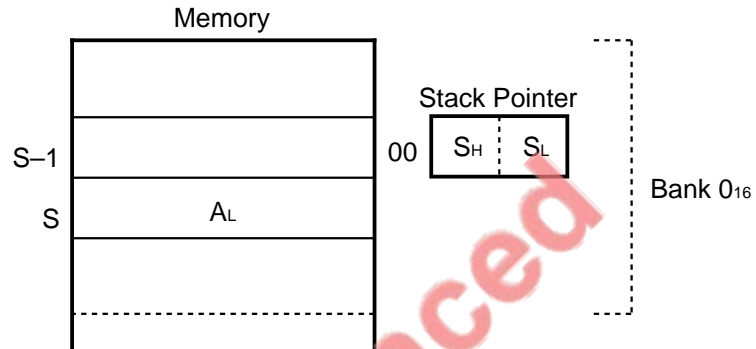

Mode : Stack addressing mode

Function : Register contents are saved to or restored from the memory location specified by the stack pointer. The stack pointer is set in bank-0.

Instruction : PEA, PEI, PER, PHA, PHB, PHD, PHG, PHP, PHT, PHX, PHY, PLA, PLB, PLD, PLP, PLT, PLX, PLY, PSH, PUL

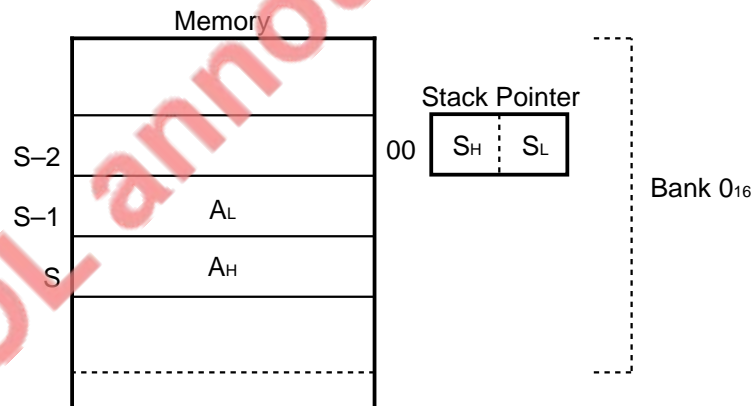

ex. : Mnemonic
PHA
(m=1)

Machine Code
48₁₆

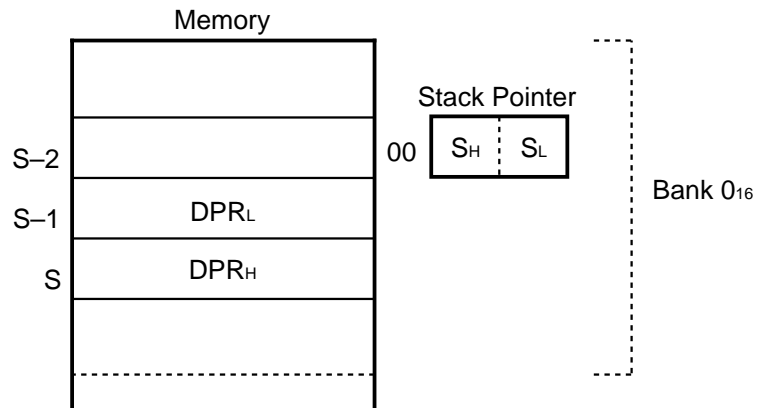

ex. : Mnemonic
PHA
(m=0)

Machine Code
48₁₆

ex. : Mnemonic
PHD

Machine Code
0B₁₆

Stack

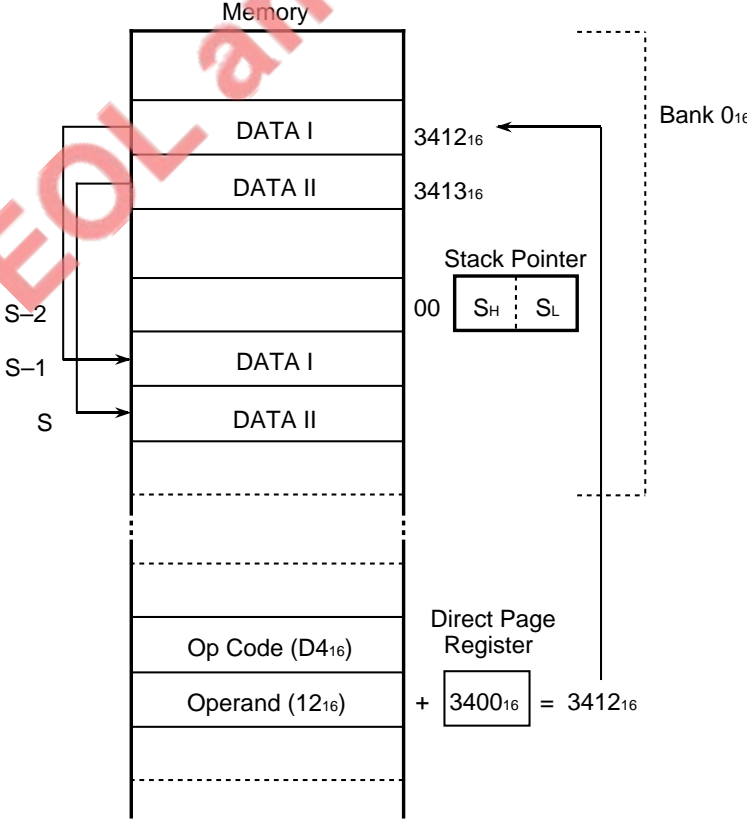

ex. : Mnemonic
PEA #1234H

Machine Code
F4₁₆ 34₁₆ 12₁₆

ex. : Mnemonic
PEI #12H

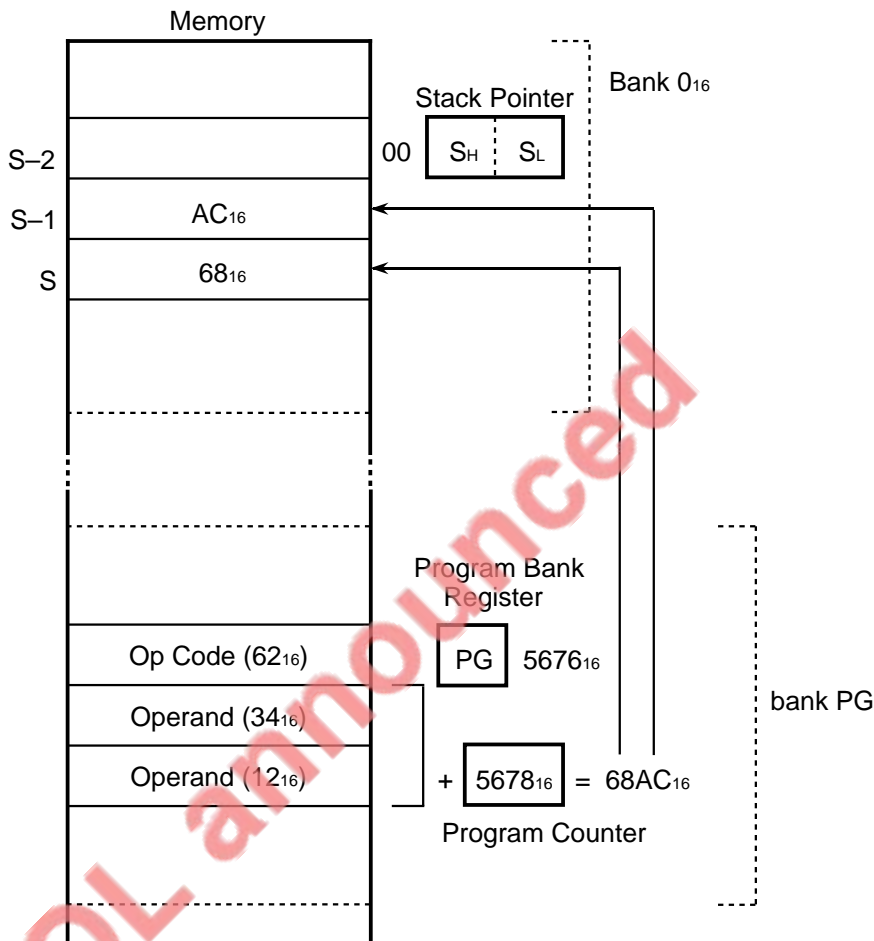

Machine Code
D4₁₆ 12₁₆

Stack

ex. : Mnemonic
PER #1234H

Machine Code
62₁₆ 34₁₆ 12₁₆

Relative

Mode : Relative addressing mode

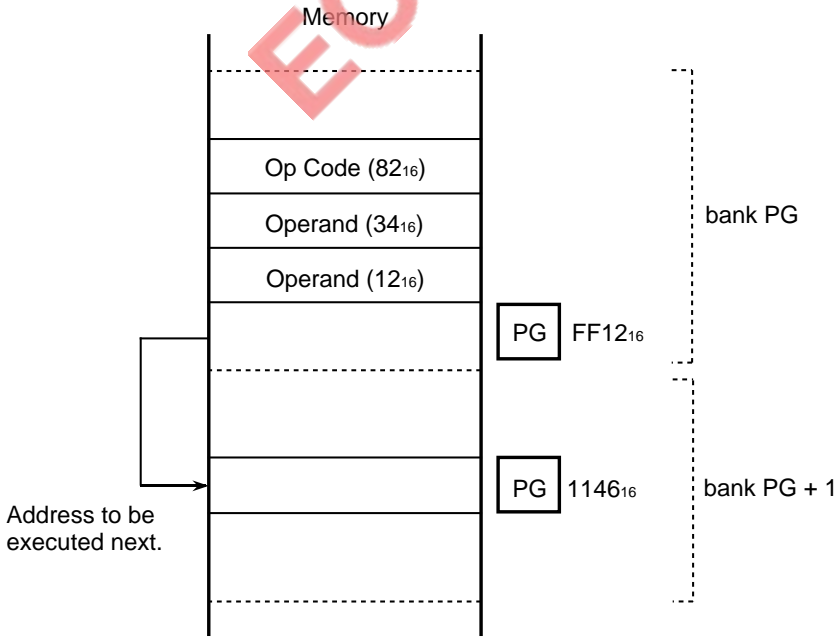

Function : Branching occurs to the address specified by the value resulting from addition of the contents of the program counter and the instruction's second byte. In the case of a long branch by the BRA instruction, a 15-bit signed numeric value formed by the contents of the instruction's second and third bytes is added to the program counter contents. If the addition generates a carry or borrow, 1 is added to or subtracted from the program bank register.

Instruction : BCC, BCS, BEQ, BMI, BNE, BPL, BRA, BVC, BVS

ex. : Mnemonic Machine Code
 BCC *-12 90₁₆ F4₁₆

ex. : Mnemonic Machine Code
 BRAL 1234H 82₁₆ 34₁₆ 12₁₆

Direct Bit Relative

Mode : Direct bit relative addressing mode

Function : Specifies the bank 0₁₆ memory location by the value obtained by adding the instruction's second byte to the direct page register's contents, and specifies the positions of multiple bits in the memory location by the bit pattern in the third and fourth bytes (the third byte only if the m flag is set to 1). Then, if the specified bits all satisfy the branching conditions, the instruction's fifth byte (or the fourth byte if the m flag is set to 1) is added to the program counter as a signed value, generating the branching destination address. If, however, addition of the instruction's second byte to the direct page register's contents result in a value that exceeds the bank 0₁₆ range, the specified location will be in bank 1₁₆.

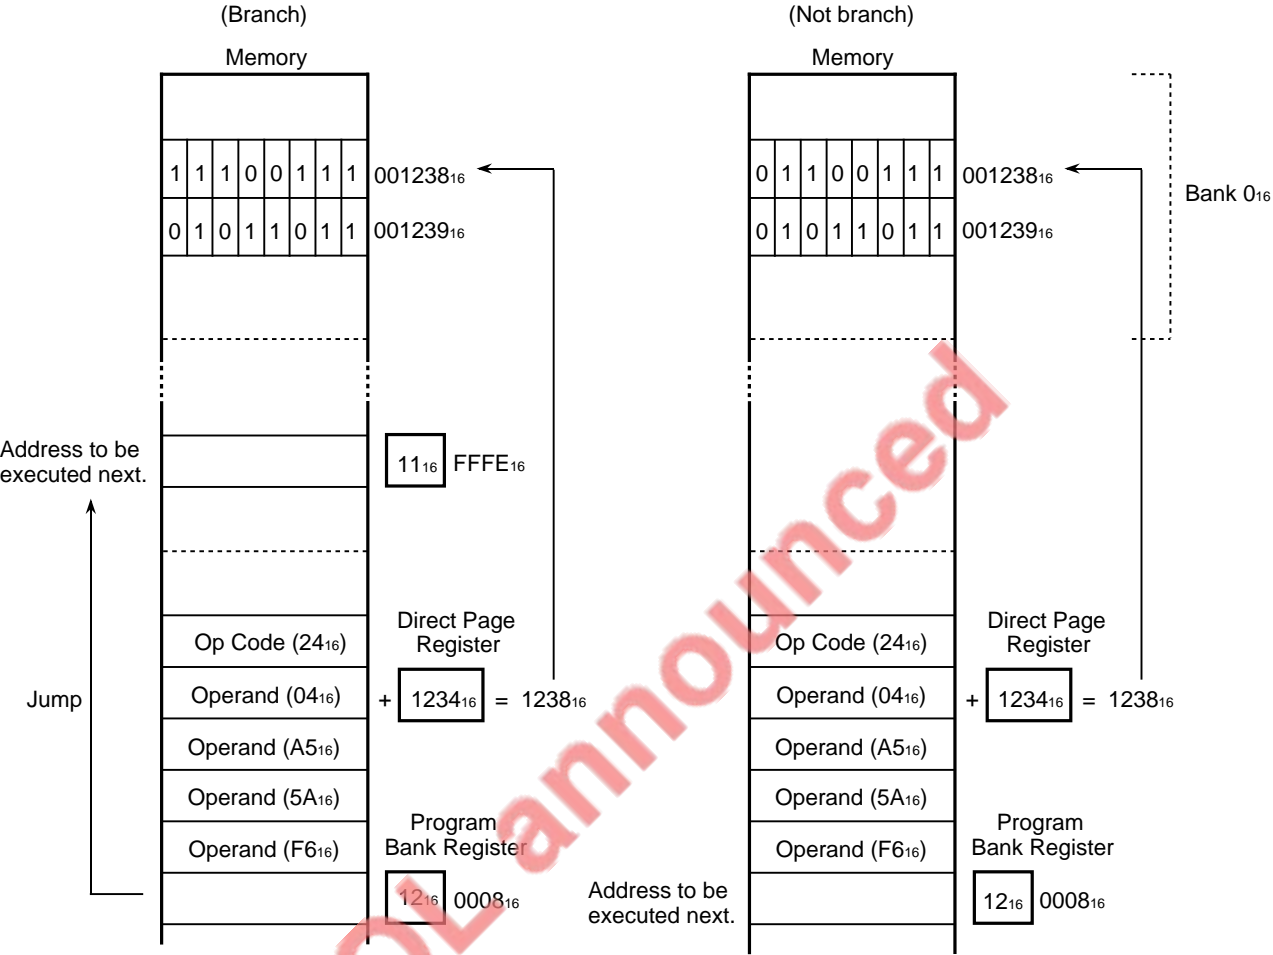

Instruction : BBC, BBS

ex. : Mnemonic Machine Code
BBS #5AH, 04H, 0F6H 24₁₆ 04₁₆ 5A₁₆ F6₁₆
(m=1)

Direct Bit Relative

ex. : Mnemonic Machine Code
BBS #5AA5H, 04H, 0F6H 24₁₆ 04₁₆ A5₁₆ 5A₁₆ F6₁₆
(m=0)

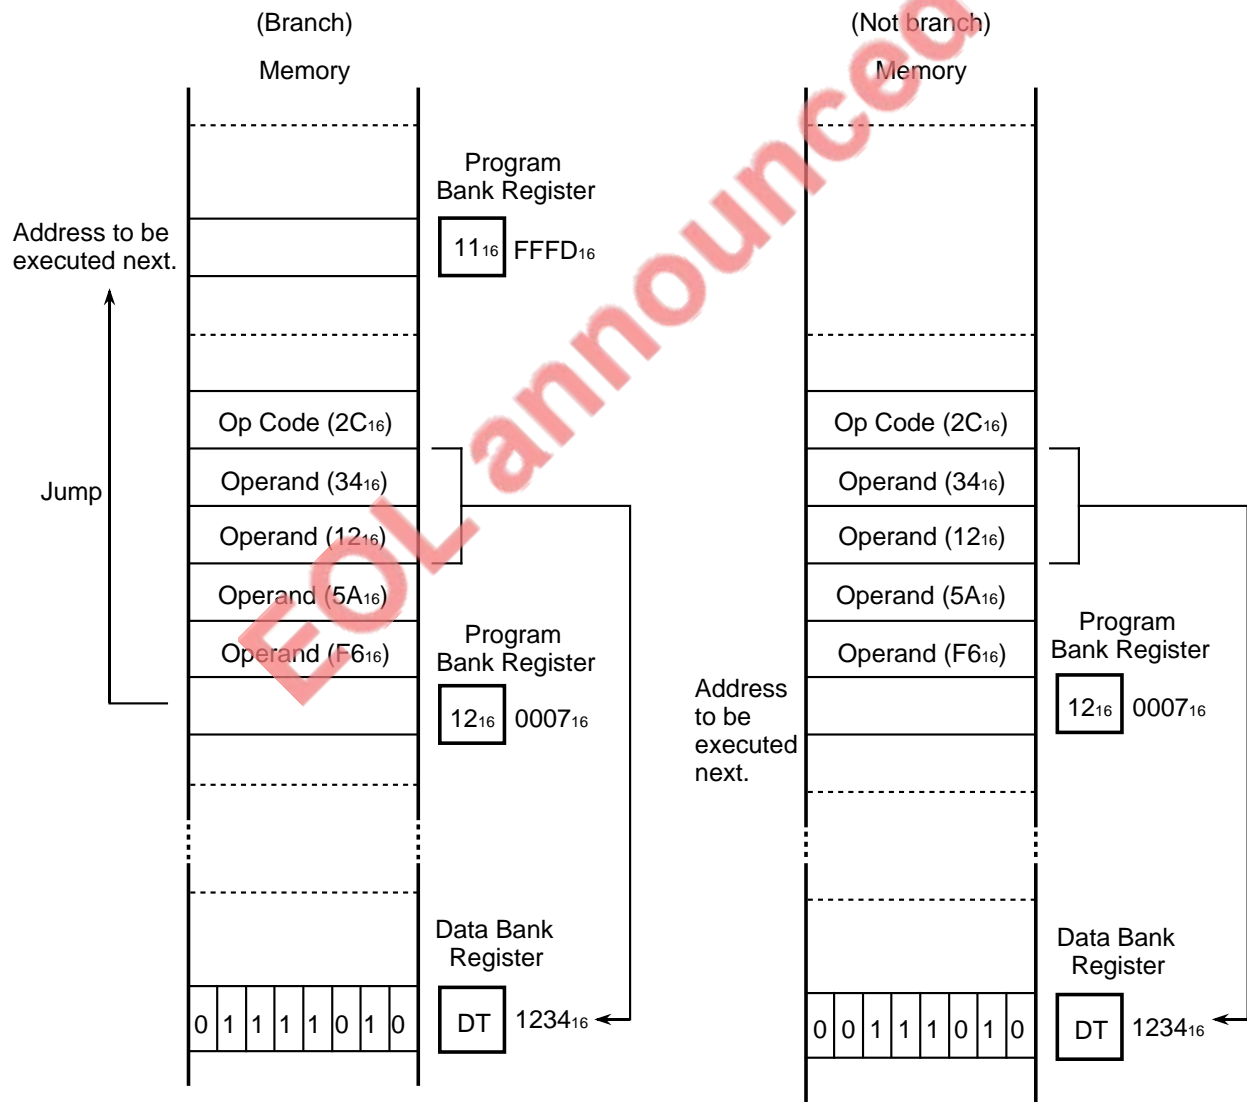

Absolute Bit Relative

Mode : Absolute bit relative addressing mode

Function : The instruction's second and third bytes and the contents of the data bank register specify the memory location, and data for the memory location's multiple bits is specified by a bit pattern in the instruction's fourth and fifth bytes (the fourth byte only if the m flag is set to 1). Then, if the specified bits all satisfy the branching conditions, the instruction's sixth byte (or the fifth byte if the m flag is set to 1) is added to the program counter as a signed value, generating the branching destination address.

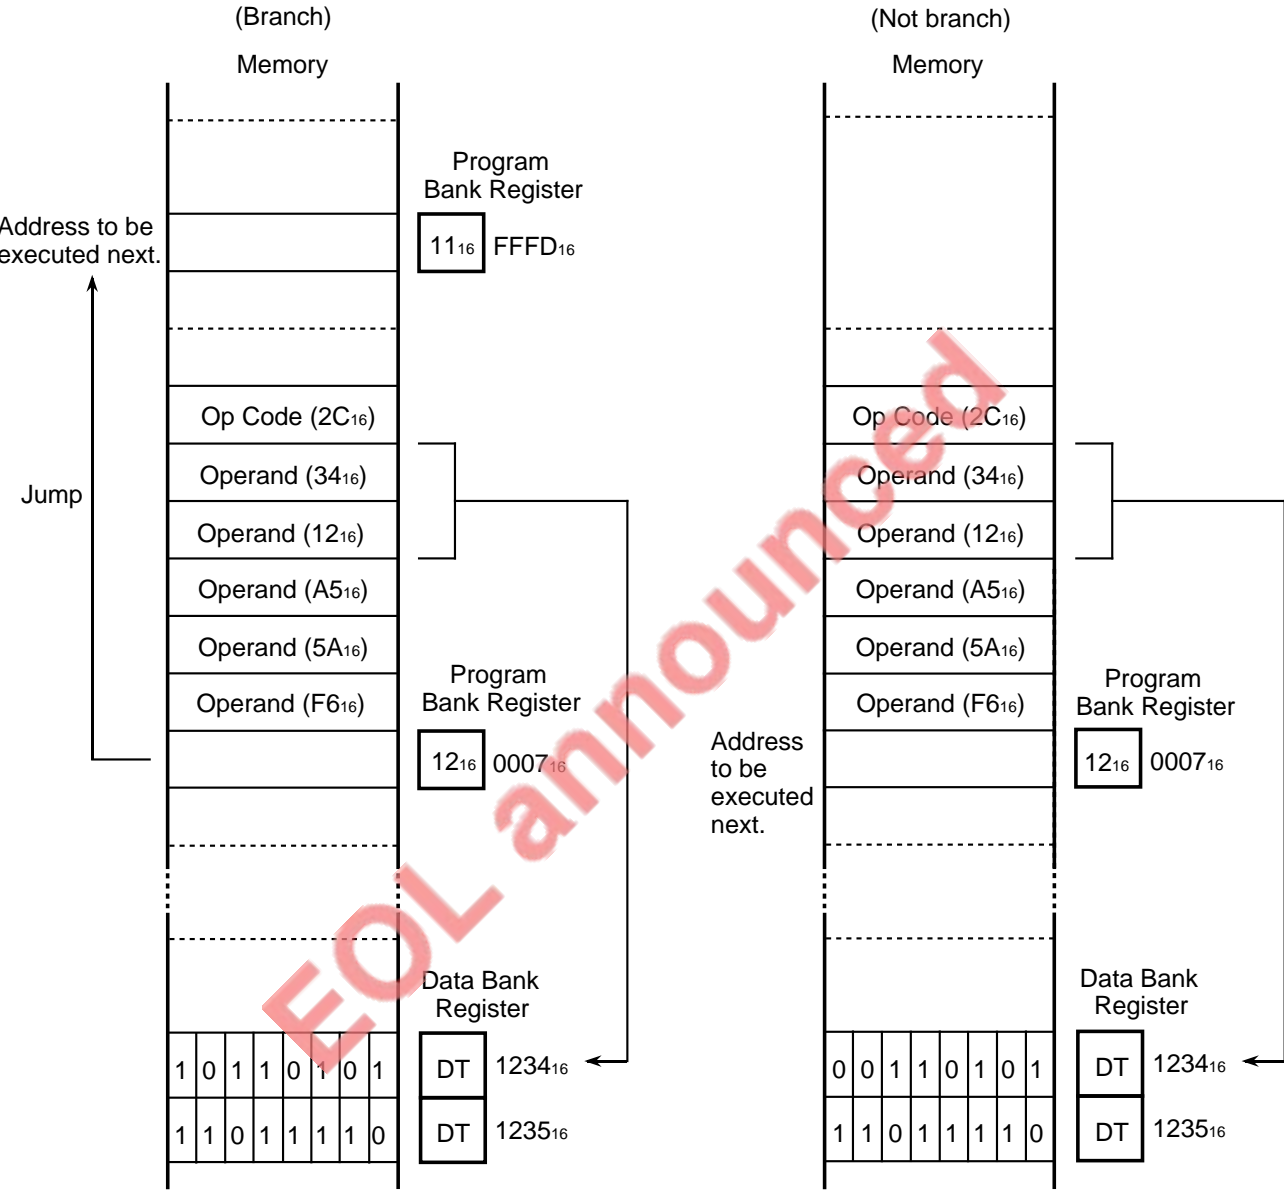

Instruction : BBC, BBS

ex. : Mnemonic Machine Code
BBS #5AH, 1234H, 0F6H 2C₁₆ 34₁₆ 12₁₆ 5A₁₆ F6₁₆
(m=1)

Absolute Bit Relative

ex. : Mnemonic Machine Code
BBS #5AA5H, 1234H, 0F6H 2C₁₆ 34₁₆ 12₁₆ A5₁₆ 5A₁₆ F6₁₆
(m=0)

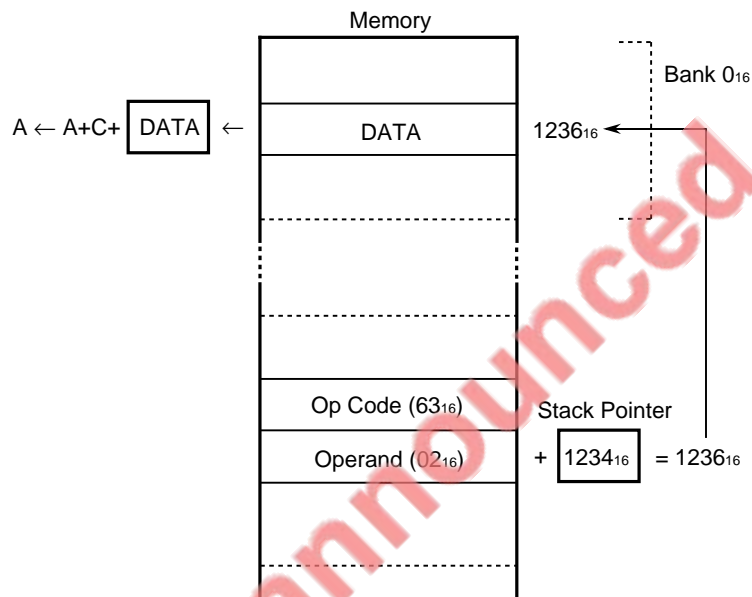

Stack Pointer Relative

Mode : Stack pointer relative addressing mode

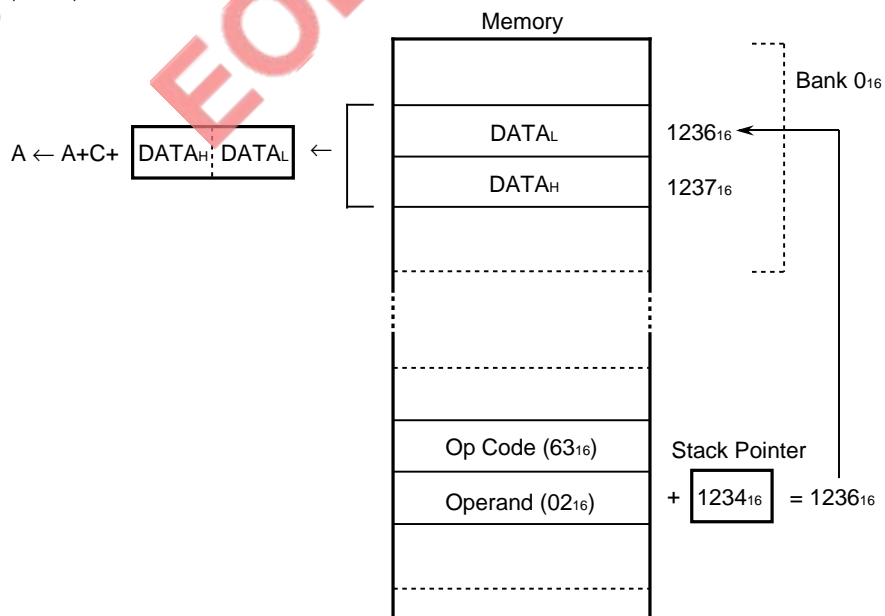

Function : The contents of a bank-0 memory location specified by the value resulting from addition of the instruction's second byte and the contents of the stack pointer become the actual data. If, however, the value obtained by adding the contents of the instruction's second byte and the stack pointer's contents exceeds the bank-0 range, the specified location will be in bank-1.

Instruction : ADC, AND, CMP, DIV, DIVS*, EOR, LDA, MPY, MPYS*, ORA, SBC, STA

ex. : Mnemonic Machine Code
 ADC A, 02H, S 63₁₆ 02₁₆
 (m=1)

ex. : Mnemonic Machine Code
 ADC A, 02H, S 63₁₆ 02₁₆
 (m=0)

Stack Pointer Relative Indirect Indexed Y

Mode : Stack pointer relative indirect indexed Y addressing mode

Function : The value obtained by adding the instruction's second byte and the contents of the stack pointer specifies 2 adjacent bytes in memory. The value obtained by adding the contents of these bytes and the contents of the index register Y specifies address of the actual data in memory bank-DT (DT is contents of data bank register). If addition of the 2 bytes in memory with the contents of the index register Y generate a carry, the bank number will be 1 larger than the contents of the data bank register.

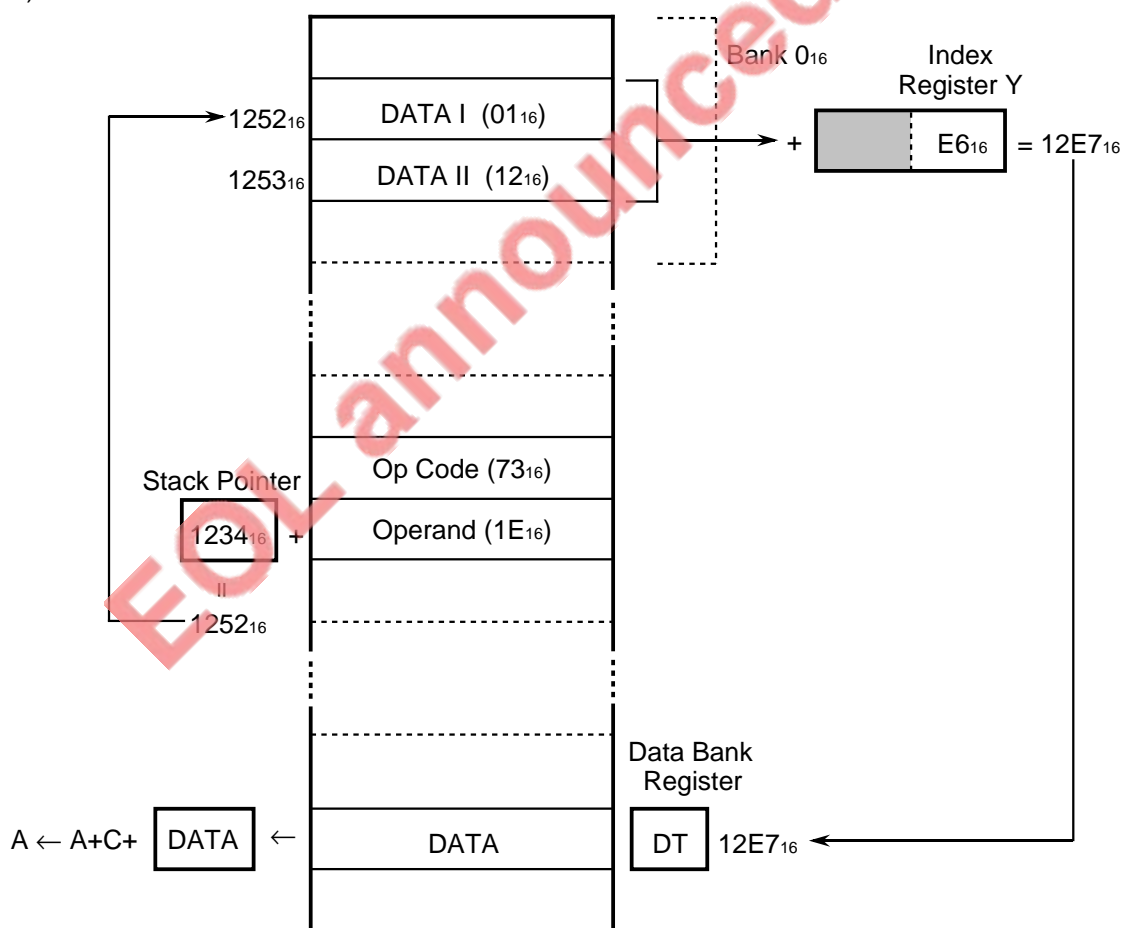

Instruction : ADC, AND, CMP, DIV, DIVS*, EOR, LDA, MPY, MPYS*, ORA, SBC, STA

ex. : Mnemonic

Machine Code

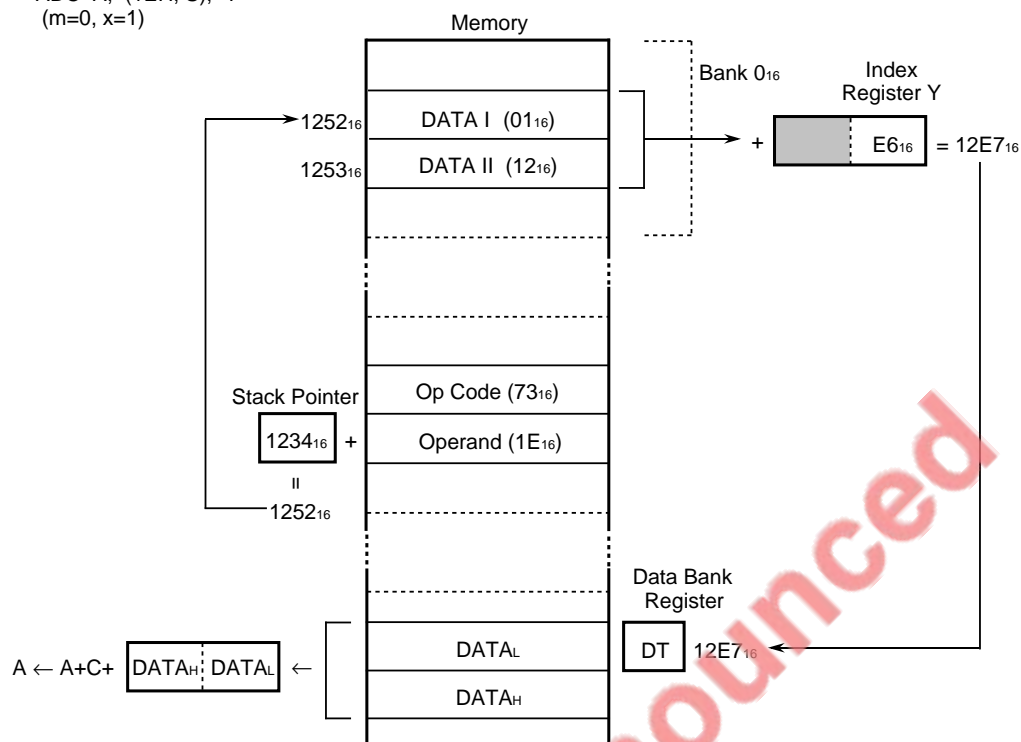

ADC A, (1EH, S), Y
(m=1, x=1)

73₁₆ 1E₁₆

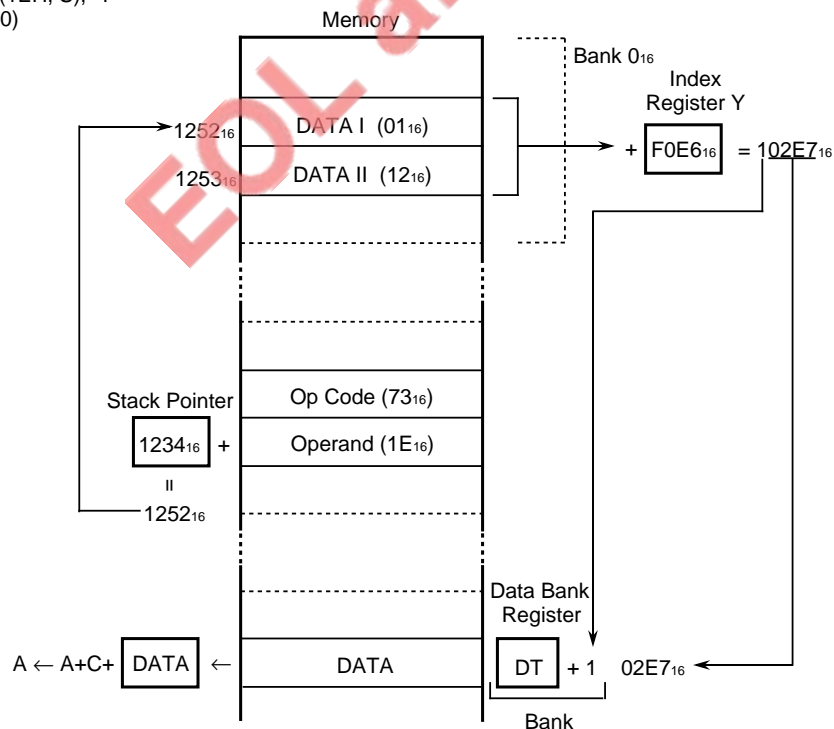

Stack Pointer Relative Indirect Indexed Y

ex. : Mnemonic Machine Code
 ADC A, (1EH, S), Y 73₁₆ 1E₁₆
 (m=0, x=1)

ex. : Mnemonic Machine Code
 ADC A, (1EH, S), Y 73₁₆ 1E₁₆
 (m=1, x=0)

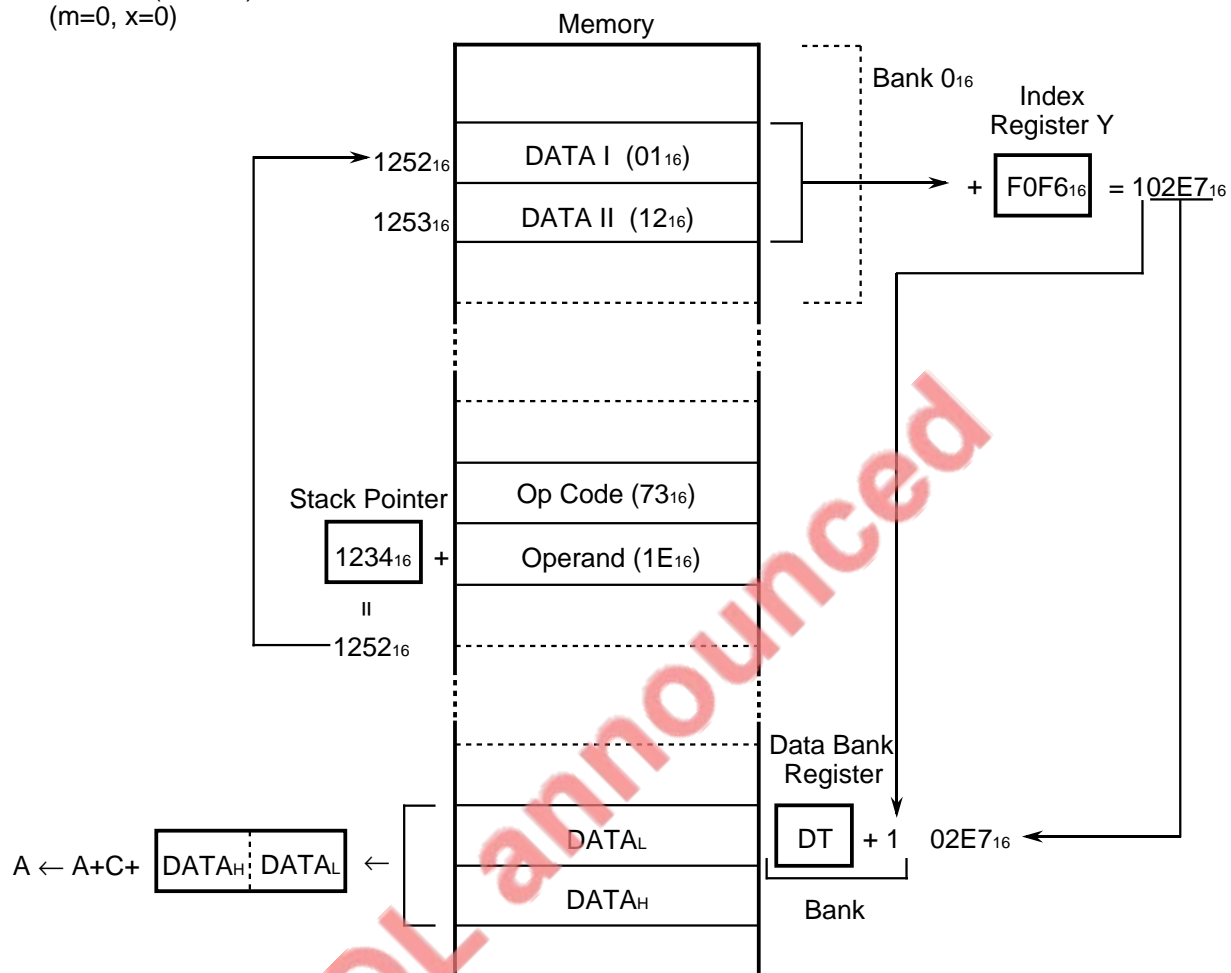

Stack Pointer Relative Indirect Indexed Y

ex. : Mnemonic

ADC A, (1EH, S), Y
(m=0, x=0)

Machine Code

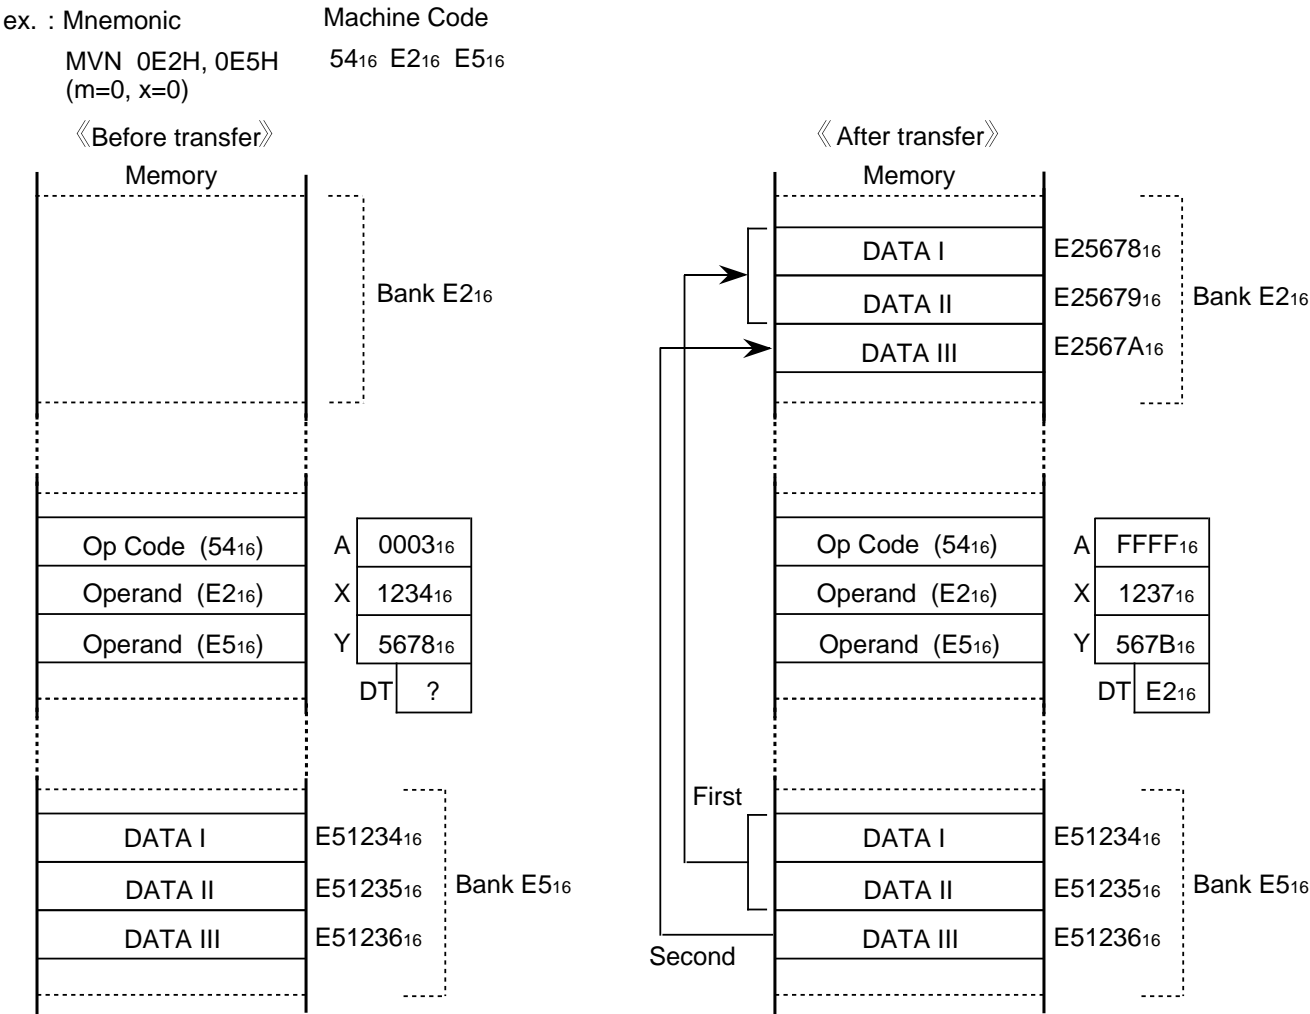

73₁₆ 1E₁₆

Mode : Block transfer addressing mode

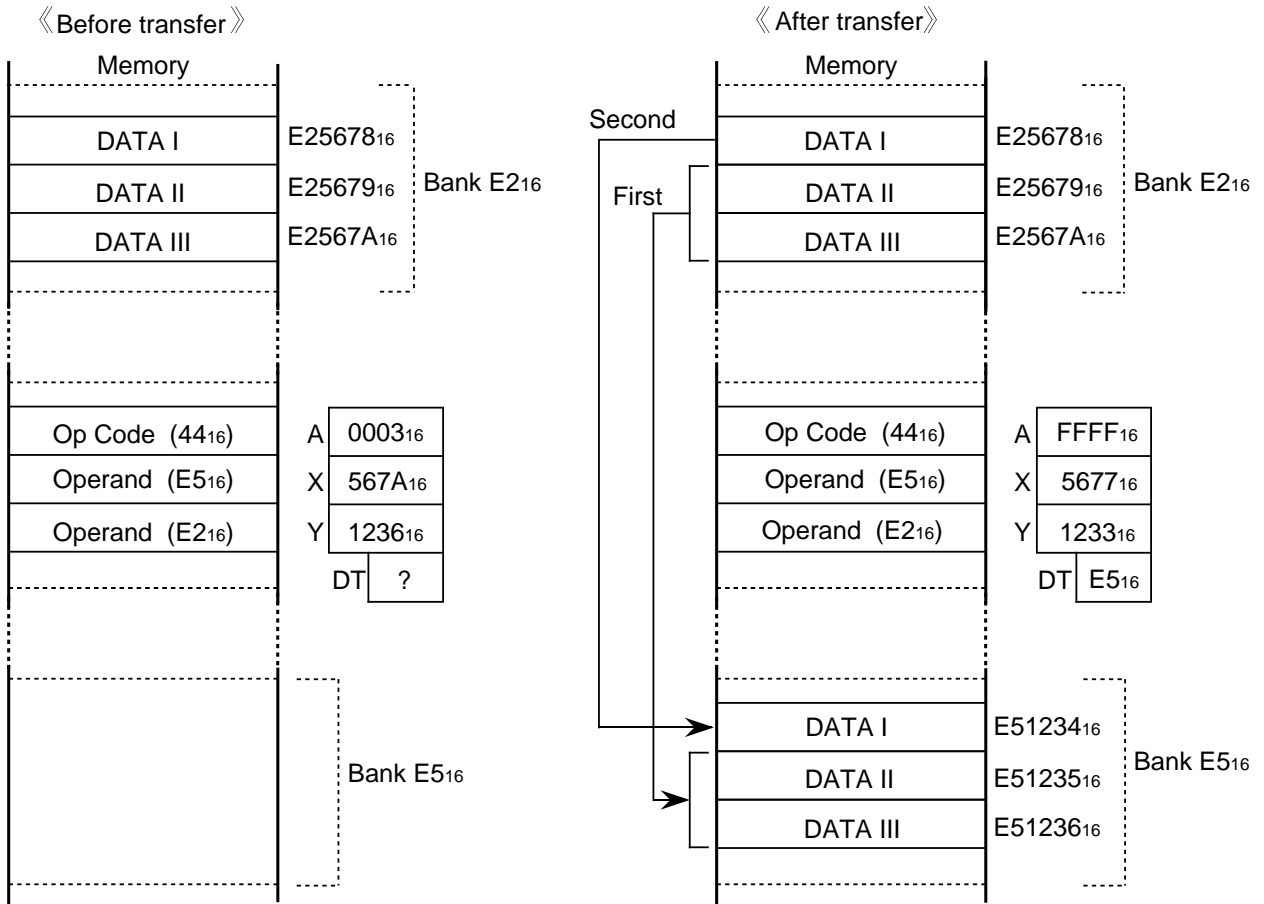

Function : The instruction's second byte specifies the transfer-to data bank, and the contents of the index register Y specify the transfer-to address within the data bank. The instruction's third byte specifies the transfer-from data bank, and the contents of the index register X specify the address in the data bank where the data to be transferred is stored. The contents of the accumulator A constitute the number of bytes to be transferred. Upon termination of transfer, the contents of the data bank register will specify the transfer-to data bank. The MVN instruction is used for transfer to lower address location. In this case, the contents of the index registers X and Y are incremented each time data is transferred. The MVP instruction is used for transfer to higher address location. In this case, the contents of the index registers X and Y are decremented each time data is transferred. The block of data to be transferred may cross over the bank boundary.

Instruction : MVN, MVP

ex. : Mnemonic
MVP 0E5H, 0E2H
(m=0, x=0)

44₁₆ E5₁₆ E2₁₆

(Note) For block transfer instruction, the transfer byte count and transfer source/destination address range change with the status of the m and x flags, but the transfer unit is unaffected. The transfer unit is word (16 bits), but only 1 byte is transferred when transferring the last byte of an odd byte transfer.

EOL announced

CHAPTER 4

INSTRUCTIONS

- 4.1 Instruction set
- 4.2 Description of instructions
- 4.3 Notes for programming

INSTRUCTIONS

4.1 Instruction set

4.1 Instruction Set

The 7700 Series, 7770 Series, and 7790 Series CPU uses the instruction set with 103 instructions. The 7750 Series CPU uses an extended instruction set (108 instructions) adding five additional instructions to their instruction set.

«Additional instructions»

Instructions	Mnemonic	Addressing mode
Multiply with sign	MPYS	Supports addressing mode equivalent to MPY instruction
Divide with sign	DIVS	Supports addressing mode equivalent to DIV instruction
Arithmetic shift right	ASR	Supports addressing mode equivalent to ASL instruction
Extension with sign	EXTS	Supported the accumulator addressing mode
Extension zero	EXTZ	

4.1.1 Data transfer instructions

The data transfer instructions move data between data and registers, between a register and the memory, between registers or between memory devices.

Category	Instruction	Description
Load	LDA	Loads the contents of memory into the accumulator.
	LDM	Loads an immediate value into the memory.
	LDT	Loads an immediate value into the data bank register.
	LDX	Loads the contents of memory into the index register X.
	LDY	Loads the contents of memory into the index register Y.
Store	STA	Stores the contents of the accumulator in the memory.
	STX	Stores the contents of the index register X in the memory.
	STY	Stores the contents of the index register Y in the memory.
Transfer	TAX	Transfers the contents of the accumulator A to the index register X.
	TXA	Transfers the contents of the index register X to the accumulator A.
	TAY	Transfers the contents of the accumulator A to the index register Y.
	TYA	Transfers the contents of the index register Y to the accumulator A.
	TSX	Transfers the contents of the stack pointer to the index register X.
	TXS	Transfers the contents of the index register X to the stack pointer.
	TAD	Transfers the contents of the accumulator A to the direct page register.
	TDA	Transfers the contents of the direct page register to the accumulator A.
	TAS	Transfers the contents of the accumulator A to the stack pointer.
	TSA	Transfers the contents of the stack pointer to the accumulator A.

INSTRUCTIONS

4.1 Instruction set

Category	Instruction	Description
Transfer	TBD	Transfers the contents of the accumulator B to the direct page register.
	TDB	Transfers the contents of the direct page register to the accumulator B.
	TBS	Transfers the contents of the accumulator B to the stack pointer.
	TSB	Transfers the contents of the stack pointer to the accumulator B.
	TBX	Transfers the contents of the accumulator B to the index register X.
	TXB	Transfers the contents of the index register X to the accumulator B.
	TBY	Transfers the contents of the accumulator B to the index register Y.
	TYB	Transfers the contents of the index register Y to the accumulator B.
	TXY	Transfers the contents of the index register X to the index register Y.
	TYX	Transfers the contents of the index register Y to the index register X.
	MVN	Transfers a block of data from the lower addresses.
	MVP	Transfers a block of data from the higher addresses.
	PSH	Saves the contents of the specified register to the stack.
Stack operation	PUL	Restores the contents of stack to the specified register.
	PHA	Saves the contents of the accumulator A to the stack.
	PLA	Restores the contents of stack to the accumulator A.
	PHP	Saves the contents of the processor status register to the stack.
	PLP	Restores the contents of stack to the processor status register.
	PHB	Saves the contents of the accumulator B to the stack.
	PLB	Restores the contents of stack to the accumulator B.
	PHD	Saves the contents of the direct page register to the stack.
	PLD	Restores the contents of stack to the direct page register.
	PHT	Saves the contents of the data bank register to stack.
	PLT	Restores the contents of stack to the data bank register.
	PHX	Saves the contents of the index register X to the stack.
	PLX	Restores the contents of stack to the index register X.
	PHY	Saves the contents of the index register Y to the stack.
	PLY	Restores the contents of stack to the index register Y.
	PHG	Saves the contents of the program bank register to the stack.
	PEA	Saves a the numeric of 2 bytes to the stack.
	PEI	Saves the contents of 2 consecutive bytes in the direct page area to the stack.
	PER	Saves the result of adding a 16-bit numeric value to the program counter contents to the stack.
Exchange	XAB	Swaps the contents of the accumulator A with the contents of the accumulator B.

INSTRUCTIONS

4.1 Instruction set

4.1.2 Arithmetic instructions

The arithmetic instructions perform addition, subtraction, multiplication, division, logical operation, comparison, rotation, shifting and sign/zero extension of register and memory contents.

The following table summarizes the arithmetic instructions supported:

Note. The instructions with the mark “ * ” can be used in the 7750 Series only.

Category	Instruction	Description
Addition, Subtraction, Multiplication, Division	ADC	Adds the contents of the accumulator, the contents of memory and the contents of the carry flag.
	SBC	Subtracts the contents of memory and the complement of the carry flag from the contents of the accumulator.
	INC	Increments the accumulator or memory contents by 1.
	DEC	Decrements the accumulator or memory contents by 1.
	INX	Increments the contents of the index register X by 1.
	DEX	Decrements the contents of the index register X by 1.
	INY	Increments the contents of the index register Y by 1.
	DEY	Decrements the contents of the index register Y by 1.
	MPY	Multiplies the contents of the accumulator A and the contents of memory.
	MPYS*	Multiply the contents of the accumulator A and the contents of memory with sign.
	DIV	Divides the numeric value whose lower byte is the contents of the accumulator A and upper byte is the contents of the accumulator B by the contents of memory.
	DIVS*	Divides the numeric value whose lower byte is the contents of the accumulator A and upper byte is the contents of the accumulator B by the contents of memory with sign.
Logical operation	AND	Performs logical AND between the contents of the accumulator and the contents of memory.
	ORA	Performs logical OR between the contents of the accumulator and the contents of memory.
	EOR	Performs logical exclusive-OR between the contents of the accumulator and the contents of memory.
Comparison	CMP	Compares the contents of the accumulator with the contents of memory.
	CPX	Compares the contents of the index register X and the contents of memory.
	CPY	Compares the contents of the index register Y and the contents of memory.
Shifting, Rotation	ASL	Shifts the contents of the accumulator or memory to the left by 1 bit.
	ASR*	Shifts the contents of the accumulator or memory holding sign to the right by 1 bit.
	LSR	Shifts the contents of the accumulator or memory to the right by 1 bit.
	ROL	Links the contents of accumulator or memory with the carry flag, and rotates the result to the left by 1 bit.
	ROR	Links the contents of accumulator or memory with the carry flag, and rotates the result to the right by 1 bit.
	RLA	Rotates the contents of the accumulator A to the left by the specified number of bits.
Extension with sign / zero	EXTS*	Extend the low-order 8 bits of accumulator to 16 bits by sign extending.
	EXTZ*	Extend the low-order 8 bits of accumulator to 16 bits by zero extending.

INSTRUCTIONS

4.1 Instruction set

4.1.3 Bit manipulation instructions

The bit manipulation instructions set the specified bits of the processor status register or memory to “1” or “0”.

The following table summarizes the bit manipulation instructions supported:

Category	Instruction	Description
Bit manipulation	CLB	Clears the specified memory bit to “0”.
	SEB	Sets the specified memory bit to “1”.
	CLP	Clears the specified bit of the processor status register’s lower byte (PSL) to “0”.
	SEP	Sets the specified bit of the processor status register’s lower byte (PSL) to “1”.

4.1.4 Flag manipulation instructions

The flag manipulation instructions set to “1” or clear to “0” the C, I, m and V flags.

The following table summarizes the flag manipulation instructions supported:

Category	Instruction	Description
Flag manipulation	CLC	Clears the contents of carry flag to “0”.
	SEC	Sets the contents of carry flag to “1”.
	CLM	Clears the contents of data length selection flag to “0”.
	SEM	Sets the contents of data length selection flag to “1”.
	CLI	Clears the contents of interrupt disable flag to “0”.
	SEI	Sets the contents of interrupt disable flag to “1”.
	CLV	Clears the contents of overflow flag to “0”.

4.1.5 Branching and return instructions

The branching and return instructions enable changing the program execution sequence.

The following table summarizes the branching and return instructions:

Category	Instruction	Description
Jump	JMP	Sets a new address in the program counter and jumps to the new address.
	BRA	Jumps to the address obtained by adding an offset value to the contents of the program counter.
	JSR	Saves the contents of the program counter to the stack and then jumps to the new address.

INSTRUCTIONS

4.1 Instruction set

Category	Instruction	Description
Branch	BBC	Causes a branch if the specified memory bits are all “0”.
	BBS	Causes a branch if the specified memory bits are all “1”.
	BCC	Causes a branch if the carry flag is set to “0”.
	BCS	Causes a branch if the carry flag is set to “1”.
	BNE	Causes a branch if the zero flag is set to “0”.
	BEQ	Causes a branch if the zero flag is set to “1”.
	BPL	Causes a branch if the negative flag is set to “0”.
	BMI	Causes a branch if the negative flag is set to “1”.
	BVC	Causes a branch if the overflow flag is set to “0”.
	BVS	Causes a branch if the overflow flag is set to “1”.
Return	RTI	Returns from the interrupt routine to the original routine.
	RTS	Returns from a subroutine to the original routine. The program bank register contents are not restored.
	RTL	Returns from a subroutine to the original routine. The program bank register contents are restored.

4.1.6 Interrupt instruction (break instruction)

The interrupt instruction executes software interrupt.

Category	Instruction	Description
Break	BRK	Executes a software interrupt.

4.1.7 Special instructions

The special instructions listed below control the clock generator circuit.

Category	Instruction	Description
Special	WIT	Stops the internal clock.
	STP	Stops the oscillator.

4.1.8 Other instruction

Category	Instruction	Description
Other	NOP	Only advances the program counter.

4.2 Description of Instructions

This section describes the 7700 Family instructions at each instruction (Note 1). To the extent possible, each instruction is described using one page per instruction. Each instruction description page is headed by the instruction mnemonic, and the pages are arranged in alphabetical order of the mnemonics. For each instruction, operation and description of the instruction (Note 2, 3), status flag changes and a listing sorted by addressing modes of the assembler coding format (Note 4), machine code, bytes-count and cycles-count (Note 5) are presented.

Note 1. The instructions with the mark “ * ” can be used in the 7750 Series only.

Note 2. In the description of instruction operation, the change in the PC (program counter) is described only for instructions affecting the processing flow.

When an instruction is executed, the length of the instruction is added to content of the PC to form the address of the next instruction to be executed. If a carry occurs during this addition, PG (program bank register) is incremented by 1.

Note 3. In the description of each instruction, [Operation] indicates the contents of each register and memory after executing the instruction. The detailed operation sequence is omitted.

Note 4. The assembler coding formats shown are general examples, and they may differ from the actual formats for the assembler used. Please be sure to refer to the mnemonic coding description in the manual for the assembler actually used for programming.

Note 5. The cycles-counts shown are the minimum possible, and they vary depending on the following conditions:

- Value of direct page register's lower byte

The cycles-count shown are for when the direct page register's lower byte (DPR_L) is 00₁₆. When using an addressing mode that uses the direct page register with DPR_L ≠ “00₁₆”, the cycles-count will be 1 more than the value shown.

- Number of bytes that have been loaded in the instruction queue buffer
- Whether the first address of the memory read/write is even- or odd-numbered in accessing the 16-bit data length.
- Accessing of an external memory are with BYTE=1 (using 8-bit external bus)
- Whether a wait is inserted in the bus cycle.

INSTRUCTIONS

4.2 Description of Instructions

The table below lists the symbols that are used in this section:

Symbol	Description
C	Carry flag
Z	Zero flag
I	Interrupt disable flag
D	Decimal operation mode flag
x	Index register length selection flag
m	Data length selection flag
V	Overflow flag
N	Negative flag
IPL	Processor interrupt priority level
+	Addition
−	Subtraction
×	Multiplication
/	Division
∧	Logical AND
∨	Logical OR
⊕	Exclusive OR
—	Negation
←	Movement to the arrow direction
→	Movement to the arrow direction
↔	Movement to the arrow direction
Acc	Accumulator
AccH	Accumulator's upper 8 bits
AccL	Accumulator's lower 8 bits
A	Accumulator A
AH	Accumulator A's upper 8 bits
AL	Accumulator A's lower 8 bits
B	Accumulator B
BH	Accumulator B's upper 8 bits
BL	Accumulator B's lower 8 bits
X	Index register X
XH	Index register X's upper 8 bits
XL	Index register X's lower 8 bits
Y	Index register Y
YH	Index register Y's upper 8 bits
YL	Index register Y's lower 8 bits
S	Stack pointer
PC	Program counter
PCH	Program counter's upper 8 bits
PCL	Program counter's lower 8 bits
REL	Relative address
PG	Program bank register
DT	Data bank register

INSTRUCTIONS

4.2 Description of Instructions

Symbol	Description
DPR	Direct page register
DPRH	Direct page register's upper 8 bits
DPRL	Direct page register's lower 8 bits
PS	Processor status register
PSH	Processor status register's upper 8 bits
PSL	Processor status register's lower 8 bits
PSn	Processor status register's n-th bit
M	Memory contents
M(n)	Contents of memory location specified by operand (1 byte data)
M(n+1,n)	Contents of memory location specified by operand (1 word data)
M(m to n)	Contents of memory location specified by operand (plural bytes data)
M(S)	Contents of memory at address indicated by stack pointer
Mb	b-th memory location
ADDR	Value of 24-bit address' lower 16-bit (A15 to A0)
BANK	Value of 24-bit address' upper 8-bit (A23 to A16)
ADG	Value of 24-bit address' upper 8-bit (A23 to A16)
ADH	Value of 24-bit address' middle 8-bit (A15 to A8)
ADL	Value of 24-bit address' lower 8-bit (A7 to A0)
IMM	Immediate value
IMM16	16-bit immediate value
IMM8	8-bit immediate value
bn	n-th bit of data
dd	8-bit offset value
i	Number of transfer bytes or rotation
i1,i2	Number of registers pushed or pulled
imm	8-bit immediate value
immHimmL	16-bit immediate value (immH specifies the upper 8-bit, and immL specifies the lower 8-bit)
ll	8-bit address value
mmll	16-bit address value (mm specifies the upper 8-bit and ll specifies the lower 8-bit)
hhmmll	24-bit address value (hh specifies the upper 8-bit, mm specifies the middle 8-bit and ll specifies the lower 8-bit)
nn	8-bit data value
n1,n2	8-bit data value (Used when coding two 8-bit data side by side)
rr	Signed 8-bit data value
rr1rr2	Signed 16-bit data value (rr1 is the upper 8-bit value, and rr2 is the lower 8-bit value)

INSTRUCTIONS

4.1 Instruction set

4.1 Instruction Set

The 7700 Series, 7770 Series, and 7790 Series CPU uses the instruction set with 103 instructions. The 7750 Series CPU uses an extended instruction set (108 instructions) adding five additional instructions to their instruction set.

«Additional instructions»

Instructions	Mnemonic	Addressing mode
Multiply with sign	MPYS	Supports addressing mode equivalent to MPY instruction
Divide with sign	DIVS	Supports addressing mode equivalent to DIV instruction
Arithmetic shift right	ASR	Supports addressing mode equivalent to ASL instruction
Extension with sign	EXTS	Supported the accumulator addressing mode
Extension zero	EXTZ	

4.1.1 Data transfer instructions

The data transfer instructions move data between data and registers, between a register and the memory, between registers or between memory devices.

Category	Instruction	Description
Load	LDA	Loads the contents of memory into the accumulator.
	LDM	Loads an immediate value into the memory.
	LDT	Loads an immediate value into the data bank register.
	LDX	Loads the contents of memory into the index register X.
	LDY	Loads the contents of memory into the index register Y.
Store	STA	Stores the contents of the accumulator in the memory.
	STX	Stores the contents of the index register X in the memory.
	STY	Stores the contents of the index register Y in the memory.
Transfer	TAX	Transfers the contents of the accumulator A to the index register X.
	TXA	Transfers the contents of the index register X to the accumulator A.
	TAY	Transfers the contents of the accumulator A to the index register Y.
	TYA	Transfers the contents of the index register Y to the accumulator A.
	TSX	Transfers the contents of the stack pointer to the index register X.
	TXS	Transfers the contents of the index register X to the stack pointer.
	TAD	Transfers the contents of the accumulator A to the direct page register.
	TDA	Transfers the contents of the direct page register to the accumulator A.
	TAS	Transfers the contents of the accumulator A to the stack pointer.
	TSA	Transfers the contents of the stack pointer to the accumulator A.

INSTRUCTIONS

4.1 Instruction set

Category	Instruction	Description
Transfer	TBD	Transfers the contents of the accumulator B to the direct page register.
	TDB	Transfers the contents of the direct page register to the accumulator B.
	TBS	Transfers the contents of the accumulator B to the stack pointer.
	TSB	Transfers the contents of the stack pointer to the accumulator B.
	TBX	Transfers the contents of the accumulator B to the index register X.
	TXB	Transfers the contents of the index register X to the accumulator B.
	TBY	Transfers the contents of the accumulator B to the index register Y.
	TYB	Transfers the contents of the index register Y to the accumulator B.
	TXY	Transfers the contents of the index register X to the index register Y.
	TYX	Transfers the contents of the index register Y to the index register X.
	MVN	Transfers a block of data from the lower addresses.
	MVP	Transfers a block of data from the higher addresses.
	PSH	Saves the contents of the specified register to the stack.
Stack operation	PUL	Restores the contents of stack to the specified register.
	PHA	Saves the contents of the accumulator A to the stack.
	PLA	Restores the contents of stack to the accumulator A.
	PHP	Saves the contents of the processor status register to the stack.
	PLP	Restores the contents of stack to the processor status register.
	PHB	Saves the contents of the accumulator B to the stack.
	PLB	Restores the contents of stack to the accumulator B.
	PHD	Saves the contents of the direct page register to the stack.
	PLD	Restores the contents of stack to the direct page register.
	PHT	Saves the contents of the data bank register to stack.
	PLT	Restores the contents of stack to the data bank register.
	PHX	Saves the contents of the index register X to the stack.
	PLX	Restores the contents of stack to the index register X.
	PHY	Saves the contents of the index register Y to the stack.
	PLY	Restores the contents of stack to the index register Y.
	PHG	Saves the contents of the program bank register to the stack.
	PEA	Saves a the numeric of 2 bytes to the stack.
	PEI	Saves the contents of 2 consecutive bytes in the direct page area to the stack.
	PER	Saves the result of adding a 16-bit numeric value to the program counter contents to the stack.
Exchange	XAB	Swaps the contents of the accumulator A with the contents of the accumulator B.

INSTRUCTIONS

4.1 Instruction set

4.1.2 Arithmetic instructions

The arithmetic instructions perform addition, subtraction, multiplication, division, logical operation, comparison, rotation, shifting and sign/zero extension of register and memory contents.

The following table summarizes the arithmetic instructions supported:

Note. The instructions with the mark “ * ” can be used in the 7750 Series only.

Category	Instruction	Description
Addition, Subtraction, Multiplication, Division	ADC	Adds the contents of the accumulator, the contents of memory and the contents of the carry flag.
	SBC	Subtracts the contents of memory and the complement of the carry flag from the contents of the accumulator.
	INC	Increments the accumulator or memory contents by 1.
	DEC	Decrements the accumulator or memory contents by 1.
	INX	Increments the contents of the index register X by 1.
	DEX	Decrements the contents of the index register X by 1.
	INY	Increments the contents of the index register Y by 1.
	DEY	Decrements the contents of the index register Y by 1.
	MPY	Multiplies the contents of the accumulator A and the contents of memory.
	MPYS*	Multiply the contents of the accumulator A and the contents of memory with sign.
	DIV	Divides the numeric value whose lower byte is the contents of the accumulator A and upper byte is the contents of the accumulator B by the contents of memory.
	DIVS*	Divides the numeric value whose lower byte is the contents of the accumulator A and upper byte is the contents of the accumulator B by the contents of memory with sign.
Logical operation	AND	Performs logical AND between the contents of the accumulator and the contents of memory.
	ORA	Performs logical OR between the contents of the accumulator and the contents of memory.
	EOR	Performs logical exclusive-OR between the contents of the accumulator and the contents of memory.
Comparison	CMP	Compares the contents of the accumulator with the contents of memory.
	CPX	Compares the contents of the index register X and the contents of memory.
	CPY	Compares the contents of the index register Y and the contents of memory.
Shifting, Rotation	ASL	Shifts the contents of the accumulator or memory to the left by 1 bit.
	ASR*	Shifts the contents of the accumulator or memory holding sign to the right by 1 bit.
	LSR	Shifts the contents of the accumulator or memory to the right by 1 bit.
	ROL	Links the contents of accumulator or memory with the carry flag, and rotates the result to the left by 1 bit.
	ROR	Links the contents of accumulator or memory with the carry flag, and rotates the result to the right by 1 bit.
	RLA	Rotates the contents of the accumulator A to the left by the specified number of bits.
Extension with sign / zero	EXTS*	Extend the low-order 8 bits of accumulator to 16 bits by sign extending.
	EXTZ*	Extend the low-order 8 bits of accumulator to 16 bits by zero extending.

INSTRUCTIONS

4.1 Instruction set

4.1.3 Bit manipulation instructions

The bit manipulation instructions set the specified bits of the processor status register or memory to “1” or “0”.

The following table summarizes the bit manipulation instructions supported:

Category	Instruction	Description
Bit manipulation	CLB	Clears the specified memory bit to “0”.
	SEB	Sets the specified memory bit to “1”.
	CLP	Clears the specified bit of the processor status register’s lower byte (PSL) to “0”.
	SEP	Sets the specified bit of the processor status register’s lower byte (PSL) to “1”.

4.1.4 Flag manipulation instructions

The flag manipulation instructions set to “1” or clear to “0” the C, I, m and V flags.

The following table summarizes the flag manipulation instructions supported:

Category	Instruction	Description
Flag manipulation	CLC	Clears the contents of carry flag to “0”.
	SEC	Sets the contents of carry flag to “1”.
	CLM	Clears the contents of data length selection flag to “0”.
	SEM	Sets the contents of data length selection flag to “1”.
	CLI	Clears the contents of interrupt disable flag to “0”.
	SEI	Sets the contents of interrupt disable flag to “1”.
	CLV	Clears the contents of overflow flag to “0”.

4.1.5 Branching and return instructions

The branching and return instructions enable changing the program execution sequence.

The following table summarizes the branching and return instructions:

Category	Instruction	Description
Jump	JMP	Sets a new address in the program counter and jumps to the new address.
	BRA	Jumps to the address obtained by adding an offset value to the contents of the program counter.
	JSR	Saves the contents of the program counter to the stack and then jumps to the new address.

INSTRUCTIONS

4.1 Instruction set

Category	Instruction	Description
Branch	BBC	Causes a branch if the specified memory bits are all “0”.
	BBS	Causes a branch if the specified memory bits are all “1”.
	BCC	Causes a branch if the carry flag is set to “0”.
	BCS	Causes a branch if the carry flag is set to “1”.
	BNE	Causes a branch if the zero flag is set to “0”.
	BEQ	Causes a branch if the zero flag is set to “1”.
	BPL	Causes a branch if the negative flag is set to “0”.
	BMI	Causes a branch if the negative flag is set to “1”.
	BVC	Causes a branch if the overflow flag is set to “0”.
	BVS	Causes a branch if the overflow flag is set to “1”.
Return	RTI	Returns from the interrupt routine to the original routine.
	RTS	Returns from a subroutine to the original routine. The program bank register contents are not restored.
	RTL	Returns from a subroutine to the original routine. The program bank register contents are restored.

4.1.6 Interrupt instruction (break instruction)

The interrupt instruction executes software interrupt.

Category	Instruction	Description
Break	BRK	Executes a software interrupt.

4.1.7 Special instructions

The special instructions listed below control the clock generator circuit.

Category	Instruction	Description
Special	WIT	Stops the internal clock.
	STP	Stops the oscillator.

4.1.8 Other instruction

Category	Instruction	Description
Other	NOP	Only advances the program counter.

4.2 Description of Instructions

This section describes the 7700 Family instructions at each instruction (Note 1). To the extent possible, each instruction is described using one page per instruction. Each instruction description page is headed by the instruction mnemonic, and the pages are arranged in alphabetical order of the mnemonics. For each instruction, operation and description of the instruction (Note 2, 3), status flag changes and a listing sorted by addressing modes of the assembler coding format (Note 4), machine code, bytes-count and cycles-count (Note 5) are presented.

Note 1. The instructions with the mark “ * ” can be used in the 7750 Series only.

Note 2. In the description of instruction operation, the change in the PC (program counter) is described only for instructions affecting the processing flow.

When an instruction is executed, the length of the instruction is added to content of the PC to form the address of the next instruction to be executed. If a carry occurs during this addition, PG (program bank register) is incremented by 1.

Note 3. In the description of each instruction, [Operation] indicates the contents of each register and memory after executing the instruction. The detailed operation sequence is omitted.

Note 4. The assembler coding formats shown are general examples, and they may differ from the actual formats for the assembler used. Please be sure to refer to the mnemonic coding description in the manual for the assembler actually used for programming.

Note 5. The cycles-counts shown are the minimum possible, and they vary depending on the following conditions:

- Value of direct page register's lower byte

The cycles-count shown are for when the direct page register's lower byte (DPR_L) is 00₁₆. When using an addressing mode that uses the direct page register with DPR_L ≠ “00₁₆”, the cycles-count will be 1 more than the value shown.

- Number of bytes that have been loaded in the instruction queue buffer
- Whether the first address of the memory read/write is even- or odd-numbered in accessing the 16-bit data length.
- Accessing of an external memory are with BYTE=1 (using 8-bit external bus)
- Whether a wait is inserted in the bus cycle.

INSTRUCTIONS

4.2 Description of Instructions

The table below lists the symbols that are used in this section:

Symbol	Description
C	Carry flag
Z	Zero flag
I	Interrupt disable flag
D	Decimal operation mode flag
x	Index register length selection flag
m	Data length selection flag
V	Overflow flag
N	Negative flag
IPL	Processor interrupt priority level
+	Addition
−	Subtraction
×	Multiplication
/	Division
∧	Logical AND
∨	Logical OR
⊕	Exclusive OR
—	Negation
←	Movement to the arrow direction
→	Movement to the arrow direction
↔	Movement to the arrow direction
Acc	Accumulator
AccH	Accumulator's upper 8 bits
AccL	Accumulator's lower 8 bits
A	Accumulator A
AH	Accumulator A's upper 8 bits
AL	Accumulator A's lower 8 bits
B	Accumulator B
BH	Accumulator B's upper 8 bits
BL	Accumulator B's lower 8 bits
X	Index register X
XH	Index register X's upper 8 bits
XL	Index register X's lower 8 bits
Y	Index register Y
YH	Index register Y's upper 8 bits
YL	Index register Y's lower 8 bits
S	Stack pointer
PC	Program counter
PCH	Program counter's upper 8 bits
PCL	Program counter's lower 8 bits
REL	Relative address
PG	Program bank register
DT	Data bank register

INSTRUCTIONS

4.2 Description of Instructions

Symbol	Description
DPR	Direct page register
DPRH	Direct page register's upper 8 bits
DPRL	Direct page register's lower 8 bits
PS	Processor status register
PSH	Processor status register's upper 8 bits
PSL	Processor status register's lower 8 bits
PSn	Processor status register's n-th bit
M	Memory contents
M(n)	Contents of memory location specified by operand (1 byte data)
M(n+1,n)	Contents of memory location specified by operand (1 word data)
M(m to n)	Contents of memory location specified by operand (plural bytes data)
M(S)	Contents of memory at address indicated by stack pointer
Mb	b-th memory location
ADDR	Value of 24-bit address' lower 16-bit (A15 to A0)
BANK	Value of 24-bit address' upper 8-bit (A23 to A16)
ADG	Value of 24-bit address' upper 8-bit (A23 to A16)
ADH	Value of 24-bit address' middle 8-bit (A15 to A8)
ADL	Value of 24-bit address' lower 8-bit (A7 to A0)
IMM	Immediate value
IMM16	16-bit immediate value
IMM8	8-bit immediate value
bn	n-th bit of data
dd	8-bit offset value
i	Number of transfer bytes or rotation
i1,i2	Number of registers pushed or pulled
imm	8-bit immediate value
immHimmL	16-bit immediate value (immH specifies the upper 8-bit, and immL specifies the lower 8-bit)
ll	8-bit address value
mmll	16-bit address value (mm specifies the upper 8-bit and ll specifies the lower 8-bit)
hhmmll	24-bit address value (hh specifies the upper 8-bit, mm specifies the middle 8-bit and ll specifies the lower 8-bit)
nn	8-bit data value
n1,n2	8-bit data value (Used when coding two 8-bit data side by side)
rr	Signed 8-bit data value
rr1rr2	Signed 16-bit data value (rr1 is the upper 8-bit value, and rr2 is the lower 8-bit value)

Function : Addition with carry

Operation : $\text{Acc} \leftarrow \text{Acc} + \text{M} + \text{C}$

When m=0

When m=1

Description : Adds the contents of the accumulator, memory and carry flag, and places the result in the accumulator.

Executed as binary addition if the decimal operation mode flag D is set to 0.

Executed as decimal addition if the decimal operation mode flag D is set to 1.

Status flags

- IPL: Not affected.
- N : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) of the operation result is 1. Otherwise, cleared to 0. Meaningless for decimal addition.
- V : Set to 1 when binary addition of signed data result in a value outside the range of -32768 to +32767 (-128 to +127 if the data length selection flag m is set to 1). Otherwise, cleared to 0. Meaningless for decimal addition.
- m : Not affected.
- x : Not affected.
- D : Not affected.
- I : Not affected.
- Z : Set to 1 when the result of operation is 0. Otherwise, cleared to 0. Meaningless for decimal addition.
- C : When the data length selection flag m is set to 0, set to 1 if binary addition exceeds +65535 or if decimal addition exceeds +9999. Otherwise, cleared to 0. When the data length selection flag m is set to 1, set to 1 if binary addition exceeds +255 or if decimal addition exceeds +99. Otherwise, cleared to 0.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Immediate	ADC A, #imm	69 ₁₆ , imm	2	2
Direct	ADC A, dd	65 ₁₆ , dd	2	4
Direct indexed X	ADC A, dd, X	75 ₁₆ , dd	2	5
Direct indirect	ADC A, (dd)	72 ₁₆ , dd	2	6
Direct indexed X indirect	ADC A, (dd, X)	61 ₁₆ , dd	2	7
Direct indirect indexed Y	ADC A, (dd), Y	71 ₁₆ , dd	2	8
Direct indirect long	ADCL A, (dd)	67 ₁₆ , dd	2	10
Direct indirect long indexed Y	ADCL A, (dd), Y	77 ₁₆ , dd	2	11
Absolute	ADC A, mml	6D ₁₆ , ll, mm	3	4
Absolute indexed X	ADC A, mml, X	7D ₁₆ , ll, mm	3	6
Absolute indexed Y	ADC A, mml, Y	79 ₁₆ , ll, mm	3	6
Absolute long	ADC A, hhmmll	6F ₁₆ , ll, mm, hh	4	6
Absolute long indexed X	ADC A, hhmmll, X	7F ₁₆ , ll, mm, hh	4	7
Stack pointer relative	ADC A, nn, S	63 ₁₆ , nn	2	5
Stack pointer relative indirect indexed Y	ADC A, (nn, S), Y	73 ₁₆ , nn	2	8

(Note 1) This table applies when using the accumulator A. If using the accumulator B, replace "A" with "B". In this case, "42₁₆" is added at the beginning of the machine code, the bytes-count increases by 1 and the cycles-count increases by 2.

(Note 2) When operating on 16-bit data in the immediate addressing mode with the data length selection flag m set to 0, the bytes-count increases by 1.

Function : Logical AND

Operation : $Acc \leftarrow Acc \wedge M$
When m=0

When m=1

Description : Performs logical AND between the contents of the accumulator and the contents of memory, and places the result in the accumulator.

Status flags

- IPL : Not affected.
- N : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) of the operation result is 1. Otherwise, cleared to 0.
- V : Not affected.
- m : Not affected.
- x : Not affected.
- D : Not affected.
- I : Not affected.
- Z : Set to 1 when the result of operation is 0. Otherwise, cleared to 0.
- C : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Immediate	AND A, #imm	29 ₁₆ , imm	2	2
Direct	AND A, dd	25 ₁₆ , dd	2	4
Direct indexed X	AND A, dd, X	35 ₁₆ , dd	2	5
Direct indirect	AND A, (dd)	32 ₁₆ , dd	2	6
Direct indexed X indirect	AND A, (dd, X)	21 ₁₆ , dd	2	7
Direct indirect indexed Y	AND A, (dd), Y	31 ₁₆ , dd	2	8
Direct indirect long	ANDL A, (dd)	27 ₁₆ , dd	2	10
Direct indirect long indexed Y	ANDL A, (dd), Y	37 ₁₆ , dd	2	11
Absolute	AND A, mml	2D ₁₆ , ll, mm	3	4
Absolute indexed X	AND A, mml, X	3D ₁₆ , ll, mm	3	6
Absolute indexed Y	AND A, mml, Y	39 ₁₆ , ll, mm	3	6
Absolute long	AND A, hhmmll	2F ₁₆ , ll, mm, hh	4	6
Absolute long indexed X	AND A, hhmmll, X	3F ₁₆ , ll, mm, hh	4	7
Stack pointer relative	AND A, nn, S	23 ₁₆ , nn	2	5
Stack pointer relative indirect indexed Y	AND A, (nn, S), Y	33 ₁₆ , nn	2	8

(Note 1) This table applies when using the accumulator A. If using the accumulator B, replace “A” with “B”. In this case, “42₁₆” is added at the beginning of the machine code, the bytes-count increases by 1 and the cycles-count increases by 2.

(Note 2) When operating on 16-bit data in the immediate addressing mode with the data length selection flag m set to 0, the bytes-count increases by 1.

Function : Arithmetic shift left

Operation : C Acc or M

 When m=0

When m=1

Description : Shifts all bits of the accumulator or memory one place to the left. Bit 0 is loaded with 0. The carry flag C is loaded from bit 15 (or bit 7 when the data length selection flag m is set to 1) of the data before the shift.

Status flags

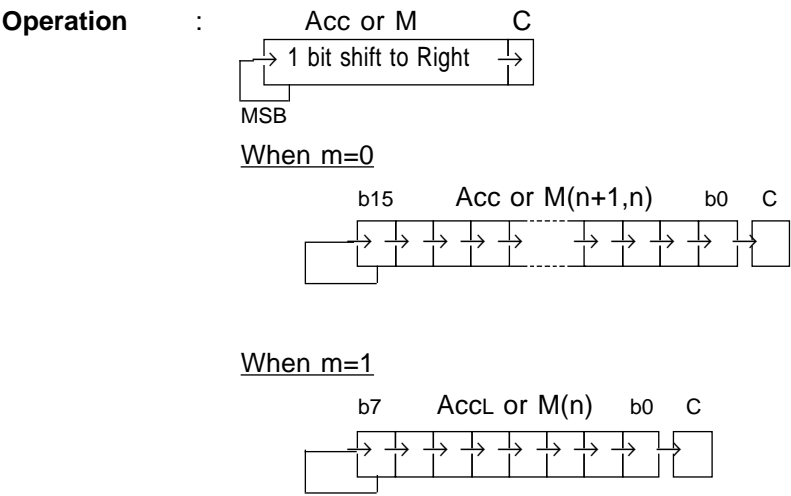

- IPL : Not affected.
- N : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) of the operation result is 1. Otherwise, cleared to 0.
- V : Not affected.
- m : Not affected.
- x : Not affected.
- D : Not affected.
- I : Not affected.
- Z : Set to 1 when the result of operation is 0. Otherwise, cleared to 0.
- C : Set to 1 when bit 15 (or bit 7 when the data length selection flag m is set to 1) before the operation is 1. Otherwise, cleared to 0.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Accumulator	ASL A	0A ₁₆	1	2
Direct	ASL dd	06 ₁₆ , dd	2	7
Direct indexed X	ASL dd, X	16 ₁₆ , dd	2	7
Absolute	ASL mml	0E ₁₆ , ll, mm	3	7
Absolute indexed X	ASL mml, X	1E ₁₆ , ll, mm	3	8

(Note 1) The accumulator addressing mode's specification in this table applies when using the accumulator A. If using the accumulator B, replace "A" with "B". In this case, "42₁₆" is added at the beginning of the machine code, the bytes-count increases by 1 and the cycles-count increases by 2.

Function : Arithmetic shift right

This instruction can be used in the 7750 Series only.

Description : Shifts all bits of the accumulator or memory one place to the right. Bit 15 (or bit 7 when the data length selection flag m is set to 1) is loaded with the value before shift. The carry flag C is loaded from bit 0 of the data before the shift.

Status flags

- IPL : Not affected.
- N : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) of the operation result is 1. Otherwise, cleared to 0.
- V : Not affected.
- m : Not affected.
- x : Not affected.
- D : Not affected.
- I : Not affected.
- Z : Set to 1 when the result of operation is 0. Otherwise, cleared to 0.
- C : Set to 1 when bit 0 before the operation is 1. Otherwise, cleared to 0.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Accumulator	ASR A	89 ₁₆ , 08 ₁₆	2	5
Accumulator	ASR B	42 ₁₆ , 08 ₁₆	2	5
Direct	ASR dd	89 ₁₆ , 06 ₁₆ , dd	3	10

Function : Branch on condition

Operation : $M_b = 0 ?$ (b is the specified bits)

When $M \wedge IMM = 0$ (True) $PC \leftarrow PC + n \pm REL$

When $M \wedge IMM \neq 0$ (False) $PC \leftarrow PC + n$

* PG changes according to the result of the above PC operation

• if carry occurs in PC : $PG \leftarrow PG + 1$

• if borrow occurs in PC : $PG \leftarrow PG - 1$

* IMM is an immediate value indicating the bit to be tested with "1".

* n is the number of instruction bytes in each addressing mode of the BBC instruction

* REL is relative value (−128 to +127) indicated by the last byte of the instruction

When $m=0$

When $m=1$

Description : The BBC instruction tests the specified bits (which may be specified simultaneously) of memory. The instruction causes a branch to the specified address when the specified bits are all 0. The branch address is specified by a relative address.

Status flags : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Direct bit relative	BBC #imm, dd, rr	34 ₁₆ , dd, imm, rr	4	7
Absolute bit relative	BBC #imm, mmll, rr	3C ₁₆ , ll, mm, imm, rr	5	8

(Note 1) The bytes-count increases by 1 when operating on 16-bit data with the data length selection flag m set to 0.

(Note 2) The cycles-count increases by 2 when a branch occurs.

Function : Branch on condition

Operation : $Mb = 1 ?$ (b is the specified bits)

When $\overline{M} \wedge IMM = 0$ (True) $PC \leftarrow PC + n \pm REL$

When $\overline{M} \wedge IMM \neq 0$ (False) $PC \leftarrow PC + n$

* PG changes according to the result of the above PC operation

• if carry occurs in PC : $PG \leftarrow PG + 1$

• if borrow occurs in PC : $PG \leftarrow PG - 1$

* n is the number of instruction bytes of the BBS instruction

* REL is relative value (−128 to +127) indicated by the last byte of the instruction

When $m=0$

When $m=1$

Description : The BBS instruction tests the specified bits (which may be specified simultaneously) of memory. The instruction causes a branch to the specified address when the specified bits are all 1. The branch address is specified by a relative address.

Status flags : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Direct bit relative	BBS #imm, dd, rr	24 ₁₆ , dd, imm, rr	4	7
Absolute bit relative	BBS #imm, mmll, rr	2C ₁₆ , ll, mm, imm, rr	5	8

(Note 1) The bytes-count increases by 1 when operating on 16-bit data with the data length selection flag m set to 0.

(Note 2) The cycles-count increases by 2 when a branch occurs.

Function : Branch on condition

Operation : $C = 0 ?$

When $C = 0$ (True)

$PC \leftarrow PC + 2 \pm REL$

When $C = 1$ (False)

$PC \leftarrow PC + 2$

* PG changes according to the result of the above PC operation

• if carry occurs in PC : $PG \leftarrow PG + 1$

• if borrow occurs in PC : $PG \leftarrow PG - 1$

* 2 is the number of instruction bytes of the BCC instruction

* REL is relative value (–128 to +127) indicated by the 2nd byte of the instruction

Description : When the carry flag C is clear (0), the BCC instruction causes a branch to the specified address. The branch address is specified by a relative address.

When the carry flag C is set (1), the program advances to next step without any action.

Status flags : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles

Addressing mode	Syntax	Machine code	Bytes	Cycles
Implied	DEY	88 ₁₆	1	2

Function : Division (Unsigned)

Operation : $A(\text{quotient}), B(\text{remainder}) \leftarrow (B, A) / M$

When m=0

When m=1

Description : When the data length selection flag m is set to 0, a 32-bit data stored in the accumulators B (upper 16 bits) and A (lower 16 bits) are divided by a 16-bit data in memory. The quotient is placed in the accumulator A, and the remainder is placed in the accumulator B.

When the data length selection flag m is set to 1, a 16-bit data stored in the lower 8 bits of the accumulators B (upper 8 bits) and A (lower 8 bits) are divided by an 8 bit data in memory. The quotient is placed in the lower 8 bits of the accumulator A, and the remainder is placed in the lower 8 bits of the accumulator B.

If an overflow occurs as a result of the operation, the V flag is set and the content of the accumulator is unpredictable.

When divisor is 0, the zero division interrupt is generated, in which case the contents of the program bank register, program counter, and processor status register are saved on the stack and a branch occurs to the address in bank-0 as specified by the zero division interrupt vector. Accumulator contents are not changed. In this case, the content of the accumulator is unchanged.

Status flags

- IPL** : Not affected.
- N** : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) of quotient from the operation is 1. Otherwise, cleared to 0.

(Note 1) When operating on 16-bit data in the immediate addressing mode with the data length selection flag m set to 0, the bytes-count increases by 1.

(Note 2) The cycles-count in this table are for 16-bit ÷ 8-bit operations. For 32-bit ÷ 16-bit operations, the cycles-count increases by 16.

(Note 3) The cycle count in this table and Note 2 are the value when the operation completes normally (no interrupt has occurred). If a zero divide interrupt has occurred, the cycle counts in the above table are decremented by 8 regardless of the data length.

Function : Division (Signed)

This instruction can be used
in the 7750 Series only.

Operation : $A(\text{quotient}), B(\text{remainder}) \leftarrow (B, A) / M$
When $m=0$

When $m=1$

* "s" means a sign bit that is the most significant bit of the data

Description : When the data length selection flag m is set to 0, a signed 32-bit data stored in the accumulators B (upper 16 bits) and A (lower 16 bits) are divided by a signed 16-bit data in memory. As a result of the operation, the quotient is stored in accumulator A and the remainder is stored in accumulator B as signed 16-bit data.

When the data length selection flag m is set to 1, a signed 16-bit data stored in the lower 8 bits of the accumulators B (upper 8 bits) and A (lower 8 bits) are divided by a signed 8 bit data in memory. As a result of the operation, the quotient is stored in low-order 8 bits of accumulator A and the remainder is stored in low-order 8 bits of accumulator B as signed 8-bit data.

The sign of remainder becomes same as dividend.

When an overflow results from this operation (the quotient exceeds the extent -32767 to $+32767$ if $m=0$ or -127 to $+127$ if $m=1$) neglect removed out, the V flag is set. In this case, the content of the accumulator is unpredictable.

When divisor is 0, the zero division interrupt is generated, in which case the contents of the processor status register are saved on the stack and a branch occurs to the address in bank 016 as specified by the zero division interrupt vector. And accumulator contents are not changed.

Status flags

- IPL** : Not affected.
- N** : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) of quotient from the operation is 1. Otherwise, cleared to 0.
* When an overflow occurs as a result of the operation or divisor is 0, N flag is not affected.
- V** : Clear to 0.
* Set to 1 when an overflow occurs
* Not affected when divisor is 0
- m** : Not affected.
- x** : Not affected.
- D** : Not affected.
- I** : Not affected.
* Set to 1 when divisor is 0

- Z : Set to 1 when the quotient from the operation is 0. Otherwise, cleared to 0. No changes occur when divisor is 0.
- * When an overflow occurs as a result of the operation or divisor is 0, Z flag is not affected.
- C : Clear to 0.
- * Set to 1 when an overflow occurs
- * Not affected when divisor is 0

Stack pointer relative indirect indexed Y	DIVS (nn, S), Y	89 ₁₆ , B3 ₁₆ , nn	3	35

(Note 1) When operating on 16-bit data in the immediate addressing mode with the data length selection flag m set to 0, the bytes-count increases by 1.

(Note 2) The cycles-count in this table are for 16-bit ÷ 8-bit operations. For 32-bit ÷ 16-bit operations, the cycles-count increases by 16.

(Note 3) The cycle count in this table and Note 2 are the value when the operation completes normally (no interrupt has occurred). If a zero divide interrupt has occurred, the cycle counts in the above table are decremented by 10 regardless of the data length.

Function : Logical EXCLUSIVE OR

Operation : $\text{Acc} \leftarrow \text{Acc} \vee M$

When $m=0$

When $m=1$

Description : Performs the logical EXCLUSIVE OR between the contents of the accumulator and the contents of memory, and places the result in the accumulator.

Status flags

- IPL : Not affected.
- N : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) of the operation result is 1. Otherwise, cleared to 0.
- V : Not affected.
- m : Not affected.
- x : Not affected.
- D : Not affected.
- I : Not affected.
- Z : Set to 1 when the result of operation is 0. Otherwise, cleared to 0.
- C : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles

Stack pointer relative	EOR A, nn, S	43 ₁₆ , nn	2	5
Stack pointer relative indirect indexed Y	EOR A, (nn, S), Y	53 ₁₆ , nn	2	8

(Note 1) This table applies when using the accumulator A. If using the accumulator B, replace "A" with "B". In this case, "42₁₆" is added at the beginning of the machine code, the bytes-count increases by 1 and the cycles-count increases by 2.

(Note 2) When operating on 16-bit data in the immediate addressing mode with the data length selection flag m set to 0, the bytes-count increases by 1.

Function : Extension with sign

This instruction can be used
in the 7750 Series only.

Operation : $AccH \leftarrow 00_{16}$ or FF_{16}
When bit 7 of $AccL=“0”$

$AccH \leftarrow 00_{16}$

When bit 7 of $AccL=“1”$

$AccH \leftarrow FF_{16}$

※ The high-order byte of Acc changes regardless of the m flag

Description : This instruction is used to extend the signed 8-bit data stored in the low-order byte of the accumulator to a 16-bit data.

If bit 7 of the accumulator is “0”, bits 8 to 15 are set to “0”. If bit 7 of the accumulator is “1”, bits 8 to 15 are set to “1”.

With this instruction, the high-order byte of accumulator changes regardless of the data length selection flag m , but the content of the data length selection flag m is unchanged.

Status flags

- IPL : Not affected.
- N : Set to 1, if bit 15 of the result of operation is 1. Otherwise, cleared to 0.
- V : Not affected.
- m : Not affected.
- x : Not affected.
- D : Not affected.
- I : Not affected.
- Z : Set to 1, if the result of operation is 0. Otherwise, cleared to 0.
- C : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Accumulator	EXTS A	89 ₁₆ , 8B ₁₆	2	8
Accumulator	EXTS B	42 ₁₆ , 8B ₁₆	2	8

Function

:

Extension zero

Operation

:

AccH ← 0016

This instruction can be used in the 7750 Series only.

Description

:

This instruction is used to extend the 8-bit data stored in the low-order byte of the accumulator to a 16-bit data.

Bits 8 to 15 of the accumulator are set to “0”.

With this instruction, the high-order byte of accumulator changes regardless of the data length selection flag m, but the content of the data length selection flag m is unchanged.

Status flags

- IPL : Not affected.
- N : Set to “0”
- V : Not affected.
- m : Not affected.
- x : Not affected.
- D : Not affected.
- I : Not affected.
- Z : Set to 1, if the result of operation is 0. Otherwise, cleared to 0.
- C : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Accumulator	EXTZ A	89 ₁₆ , AB ₁₆	2	5
Accumulator	EXTZ B	42 ₁₆ , AB ₁₆	2	5

Function : Increment

Operation : $Acc \leftarrow Acc + 1$ or $M \leftarrow M + 1$
When $m=0$

When $m=1$

Description : Adds 1 to the contents of the accumulator or memory.

Status flags

- IPL : Not affected.
- N : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) of the operation result is 1. Otherwise, cleared to 0.
- V : Not affected.
- m : Not affected.
- x : Not affected.
- D : Not affected.
- I : Not affected.
- Z : Set to 1 when the result of operation is 0. Otherwise, cleared to 0.
- C : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Accumulator	INC A	3A ₁₆	1	2
Direct	INC dd	E6 ₁₆ , dd	2	7
Direct indexed X	INC dd, X	F6 ₁₆ , dd	2	7
Absolute	INC mml	EE ₁₆ , ll, mm	3	7
Absolute indexed X	INC mml, X	FE ₁₆ , ll, mm	3	8

(Note 1) The accumulator addressing mode's specification in this table applies when using the accumulator A. If using the accumulator B, replace "A" with "B". In this case, "42₁₆" is added at the beginning of the machine code, the bytes-count increases by 1 and the cycles-count increases by 2.

Function : Increment

Operation : $X \leftarrow X + 1$
When x=0

When x=1

Description : Adds 1 to the contents of the index register X.

Status flags

- IPL : Not affected.
- N : Set to 1 when bit 15 (or bit 7 if the index register length selection flag x is set to 1) of the operation result is 1. Otherwise, cleared to 0.
- V : Not affected.
- m : Not affected.
- x : Not affected.
- D : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Implied	INY	C8 ₁₆	1	2

Function : Jump always

Operation : [PG], PC ← specified address (absolute or indirect)

When the addressing mode is ...

absolute addressing mode,

PC ← ADDR

absolute long addressing mode,

PC ← ADDR

PG ← BANK

absolute indirect addressing mode,

PC ← M(ADDR+1, ADDR)

absolute indirect long addressing mode,

PC ← M(ADDR+1, ADDR)

PG ← M(ADDR+2)

absolute indexed X indirect addressing mode,

PC ← M(ADDR+X+1, ADDR+X)

* ADDR indicates the low-order 16 bits of a 24-bit address and is specified by bytes 2 and 3 of the instruction.

* BANK is the high-order 8 bits of a 24-bit address and is specified by byte 4 of the instruction.

Description : The JMP instruction causes a jump to the address specified for the addressing mode in use. When this instruction is used in addressing mode other than absolute long, the content of PG is incremented by 1 and the branch destination becomes the next bank if the last byte of the instruction is at the topmost address (XXXXFF₁₆) of a bank or if the instruction spans across banks.

Status flags : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Absolute	JMP mml	4C ₁₆ , ll, mm	3	2
Absolute long	JMPL hhmmll	5C ₁₆ , ll, mm, hh	4	4
Absolute indirect	JMP (mml)	6C ₁₆ , ll, mm	3	4
Absolute indirect long	JMPL (mml)	DC ₁₆ , ll, mm	3	8
Absolute indexed X indirect	JMP (mml, X)	7C ₁₆ , ll, mm	3	6

Function : Jump to subroutine

Operation : $\text{Stack} \leftarrow [\text{PG}], \text{PC}$
 $[\text{PG}], \text{PC} \leftarrow \text{specified address (absolute or indirect)}$

When the addressing mode is ...

absolute addressing mode.

$\text{PC} \leftarrow \text{PC} + 3$ (S) in just after instruction execution
 $\text{M}(\text{S}, \text{S}-1) \leftarrow \text{PC}$ (S) in just before instruction execution
 $\text{S} \leftarrow \text{S} - 2$
 $\text{PC} \leftarrow \text{ADDR}$

Stack

PCH

absolute long addressing mode.

$\text{PC} \leftarrow \text{PC} + 4$ (S) in just after instruction execution
 $\text{M}(\text{S to S}-2) \leftarrow \text{PG}, \text{PC}$
 $\text{S} \leftarrow \text{S} - 3$ (S) in just before instruction execution
 $\text{PC} \leftarrow \text{ADDR}$
 $\text{PG} \leftarrow \text{BANK}$

Stack
PCL
PCH
PG

absolute indexed X indirect addressing mode.

$\text{PC} \leftarrow \text{PC} + 3$ (S) in just after instruction execution
 $\text{M}(\text{S}, \text{S}-1) \leftarrow \text{PC}$
 $\text{S} \leftarrow \text{S} - 2$ (S) in just before instruction execution
 $\text{PC} \leftarrow \text{M}(\text{ADDR} + \text{X} + 1, \text{ADDR} + \text{X})$

Stack
PCL
PCH

* ADDR indicates the low-order 16 bits of a 24-bit address and is specified by bytes 2 and 3 of the instruction.

* BANK is the high-order 8 bits of a 24-bit address and is specified by byte 4 of the instruction.

Description : The contents of the program counter PC (or the program bank register PG and the program counter PC if absolute long addressing mode) are first saved on the stack, then a jump occurs to the address shown for each addressing mode.

When this instruction is used in addressing mode other than absolute long, the content of PG is incremented by 1 and the branch destination becomes the next bank if the last byte of the instruction is at the topmost address (XXFFFF₁₆) of a bank or if the instruction spans across banks.

Status flags : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Absolute	JSR mml	20 ₁₆ , ll, mm	3	6
Absolute long	JSRL hhmml	22 ₁₆ , ll, mm, hh	4	8
Absolute indexed X indirect	JSR (mml, X)	FC ₁₆ , ll, mm	3	8

Function : Load

Operation : $\text{Acc} \leftarrow M$
When m=0

When m=1

Description : Loads the contents of memory into the accumulator.

Status flags

- IPL : Not affected.
 N : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) of the operation result is 1. Otherwise, cleared to 0.

Stack pointer relative	MPYS nn, S	89 ₁₆ , 83 ₁₆ , nn	3	21
Stack pointer relative indirect indexed Y	MPYS (nn, S), Y	89 ₁₆ , 93 ₁₆ , nn	3	24

(Note 1) When operating on 16-bit data in the immediate addressing mode with the data length selection flag m set to 0, the bytes-count increases by 1.

(Note 2) The cycles-count in this table are for 8-bit × 8-bit multiplications with the same sign. If the multiplier and multiplicand have different signs, three additional cycles are required. For 16-bit × 16-bit multiplications, the cycles-count increases by 8.

Function : Move

Operation : $M(n \text{ to } n + k) \leftarrow M(m \text{ to } m + k)$

$A = 0$?

When $A=0$

Instruction execution complete

When $A \neq 0$

Repeat operation

$M(DT_d: Y) \leftarrow M(DT_s: X)$

$X \leftarrow X + 2$

$Y \leftarrow Y + 2$

$A \leftarrow A - 2$

* DT_d indicates the transfer destination bank and is specified with the second byte of the instruction.

* DT_s indicates the transfer source bank and is specified with the third byte of the instruction.

* Values set in register before transfer

A: Transfer byte count

When $m=0$ The value 0 to 65535 can be set

When $m=1$ The value 0 to 255 can be set

X: Transfer source area beginning (lowermost) address

When $x=0$ The value 0 to 65535 can be set

When $x=1$ The value 0 to 255 can be set (Note 1)

Y: Transfer destination area beginning (lowermost) address

When $x=0$ The value 0 to 65535 can be set

When $x=1$ The value 0 to 255 can be set (Note 1)

* Content of register after transfer

A: $FFFF_{16}$

X: Transfer source area end (highermost) address + 1

Y: Transfer destination area beginning (highermost) address + 1

DT: Bank number of transfer destination

* Transfer is always performed two bytes at a time. Therefore, in the case of a 16-bit bus, the transfer time is shorter when transfer start addresses are even compared to when they are both odd addresses.

Note 1. This instruction is recommended to use at the $x="0"$. Data in the area between $XX00_{16}$ and $XXFF_{16}$ can be only used because the higher bytes of index registers X and Y are not affected at $x="1"$.

Description : Normally, a block of data is transferred from upper addresses to lower addresses. The transfer is performed in the ascending address order of the block being transferred. The target bank is specified by the instruction's second byte, and the address within the target bank is specified by the contents of the index register Y. The source bank is specified by the instruction's third byte, and the address within the source bank is specified by the contents of the index register X. The accumulator A is loaded with the bytes-count of the data to be transferred. As each byte of data is transferred, the index registers X and Y are incremented by 1, so that the index register X will become a value equal to 1 larger than the source address of the last byte transferred and the index register Y will become a value equal to 1 larger than the target address of the last byte received. The data bank register DT will become the target bank number, and the accumulator A will become $FFFF_{16}$.

Status flags : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Block transfer	MVN n_1, n_2	$54_{16}, n_1, n_2$	3	$7+(i/2) \times 7$

(Note 1) The cycles-count shown above is for when the number of bytes transferred, i , is an even number. If i is an odd number, the cycles-count is obtained as follows:

$$7 + (i \div 2) \times 7 + 4.$$

Note that $(i \div 2)$ denotes the integer part of the result of dividing i by 2.

Function : Move

Operation : $M(n - k \text{ to } n) \leftarrow M(m - k \text{ to } m)$

$A = 0$?

When $A=0$

Instruction execution complete

A: $FFFF_{16}$

X: Transfer source area end (lowermost) address - 1

Y: Transfer destination area beginning (lowermost) address - 1

DT: Bank number of transfer destination

* Transfer is always performed two bytes at a time. Therefore, in the case of a 16-bit bus, the transfer time is shorter when transfer start addresses are odd compared to when they are both even addresses.

Note 1. This instruction is recommended to use at the $x=0$. Data in the area between $XX00_{16}$ and $XXFF_{16}$ can be only used because the higher bytes of index registers X and Y are not affected at $x=1$.

Description : Normally, a block of data is transferred from lower addresses to upper addresses. The transfer is performed in the descending address order of the block being transferred. The target bank is specified by the instruction's second byte, and the address within the target bank is specified by the contents of the index register Y. The source bank is specified by the instruction's third byte, and the address within the source bank is specified by the contents of the index register X. The accumulator A is loaded with the bytes-count of the data to be transferred. As each byte of data is transferred, the index registers X and Y are decremented by 1, so that the index register X will become a value equal to 1 less than the source address of the last byte transferred and the index register Y will become a value equal to 1 smaller than the target address of the last byte received. The data bank register DT will become the target bank number, and the accumulator A will become $FFFF_{16}$.

Status flags : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Block transfer	MVP n_1, n_2	$44_{16}, n_1, n_2$	3	$9+(i/2) \times 7$

(Note 1) The cycles-count shown above is for when the number of bytes transferred, i , is an even number. If i is an odd number, the cycles-count is obtained as follows:

$$9 + (i \div 2) \times 7 + 5.$$

Note that $(i \div 2)$ denotes the integer part of the result of dividing i by 2.

Function : No operation

Operation : $PC \leftarrow PC + 1$
* PG also changes depending on the result of the above operation on PC.
If a carry occurs in PC: $PG \leftarrow PG + 1$

Description : This instruction only causes the program counter to be incremented by 1 and nothing else.

Status flags : Not affected.

Function : Stack manipulation (push)

Operation : $\text{Stack} \leftarrow \text{Specified register of A, B, X, Y, DPR, DT, PG, PS}$

$$\begin{matrix} M(S \text{ to } S - n) \leftarrow & \text{A,} & \text{B,} & \text{X,} & \text{Y,} & \text{DPR,} & \text{DT,} & \text{PG,} & \text{PS} \\ & \text{order to save} & \text{①} & \text{②} & \text{③} & \text{④} & \text{⑤} & \text{⑥} & \text{⑦} & \text{⑧} \\ S \leftarrow & S - n - 1 \end{matrix}$$

- * The immediate value in the second byte of the instruction is used to specify the registers to be saved.
- * Among the registers being saved, the following registers are affected by the flags just before the instruction is executed.
 - A, B registers
 - When m=0 : The high-order and low-order bytes of the register are saved.
 - When m=1 : The low-order bytes of the register are saved.
 - X, Y registers
 - When x=0 : The high-order and low-order bytes of the register is saved.
 - When x=1 : The low-order byte of the register is saved.
- * n indicates the number of data bytes to be saved.

Description : This instruction's second byte specifies the registers to be saved. The registers corresponding to the bits in the second byte that are 1 are saved on the stack. The bit and register correspondence is as shown below:

b7				b0			
PS	PG	DT	DPR	Y	X	B	A
← Direction to save on the stack							

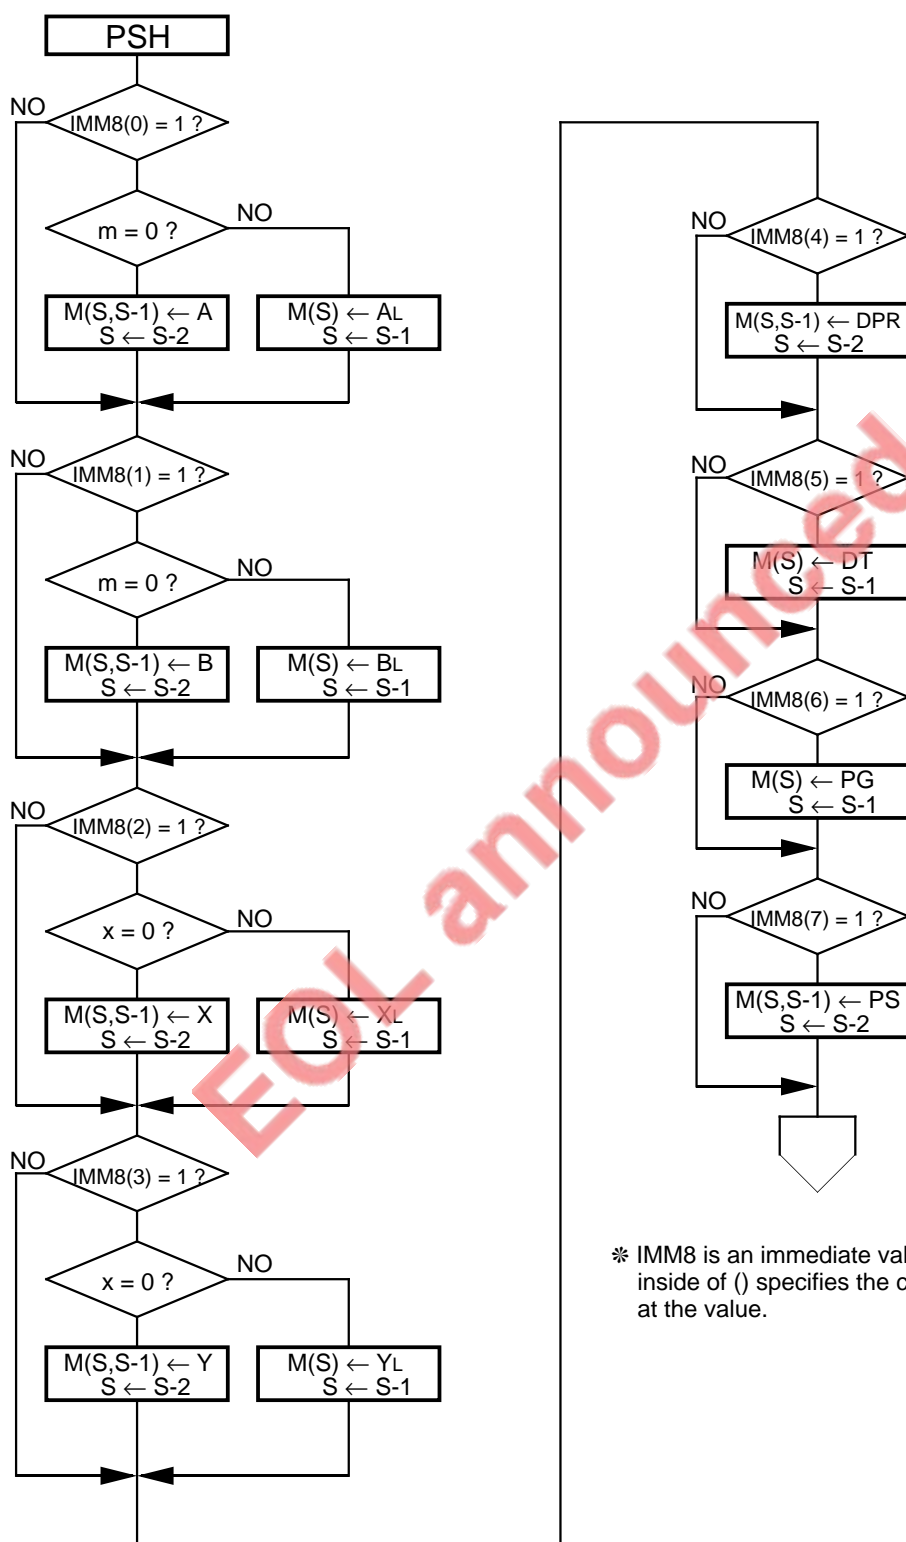

When saving the registers to stack, registers A and B are affected by the m flag and registers X and Y are affected by the x flag.

Status flags : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Stack	PSH #nn	EB ₁₆ , nn	2	12+2X _{i1} +i ₂

(Note 1) To the cycles-count shown above, the values shown below are added depending on the registers being saved. The count is 12 cycles when no registers are saved. i₁ in above table represents the number of registers (chosen from A, B, X, Y, DPR and PS) to be saved, and i₂ represents the number of registers (chosen from DT and PG) to be saved.

Register type	PS	PG	DT	DPR	Y	X	B	A
Cycles-count	2	1	1	2	2	2	2	2

* IMM8 is an immediate value in 1-byte and inside of () specifies the contents of the bit at the value.

Function : Stack manipulation (pull)

Operation : Specified register of A, B, X, Y, DPR, DT, PG, PS ← Stack

A, B, X, Y, DPR, DT, PG, PS ← M(S + 1 to S + n)
 ① ② ③ ④ ⑤ ⑥ ⑦ ⑧ order to restore
 S ← S + n

* The immediate value in the second byte of the instruction is used to specify the registers to be restored.

* Among the registers being restored, the following registers are affected by the flags in the restored PS or the flags just before the instruction is executed.

● A, B registers

When m=0 : The high-order and low-order bytes of the register are restored.

When m=1 : The low-order bytes of the register are restored.

● X, Y registers

When x=0 : The high-order and low-order bytes of the register is restored.

When x=1 : The low-order byte of the register is restored.

* n indicates the number of data bytes to be restored.

Description : This instruction's second byte specifies the registers to be restored. The registers corresponding to the bits in the second byte that are 1 are restored from the stack. The bit and register correspondence is as shown below:

b7							b0
PS		DT	DPR	Y	X	B	A

Direction to restore from the stack →

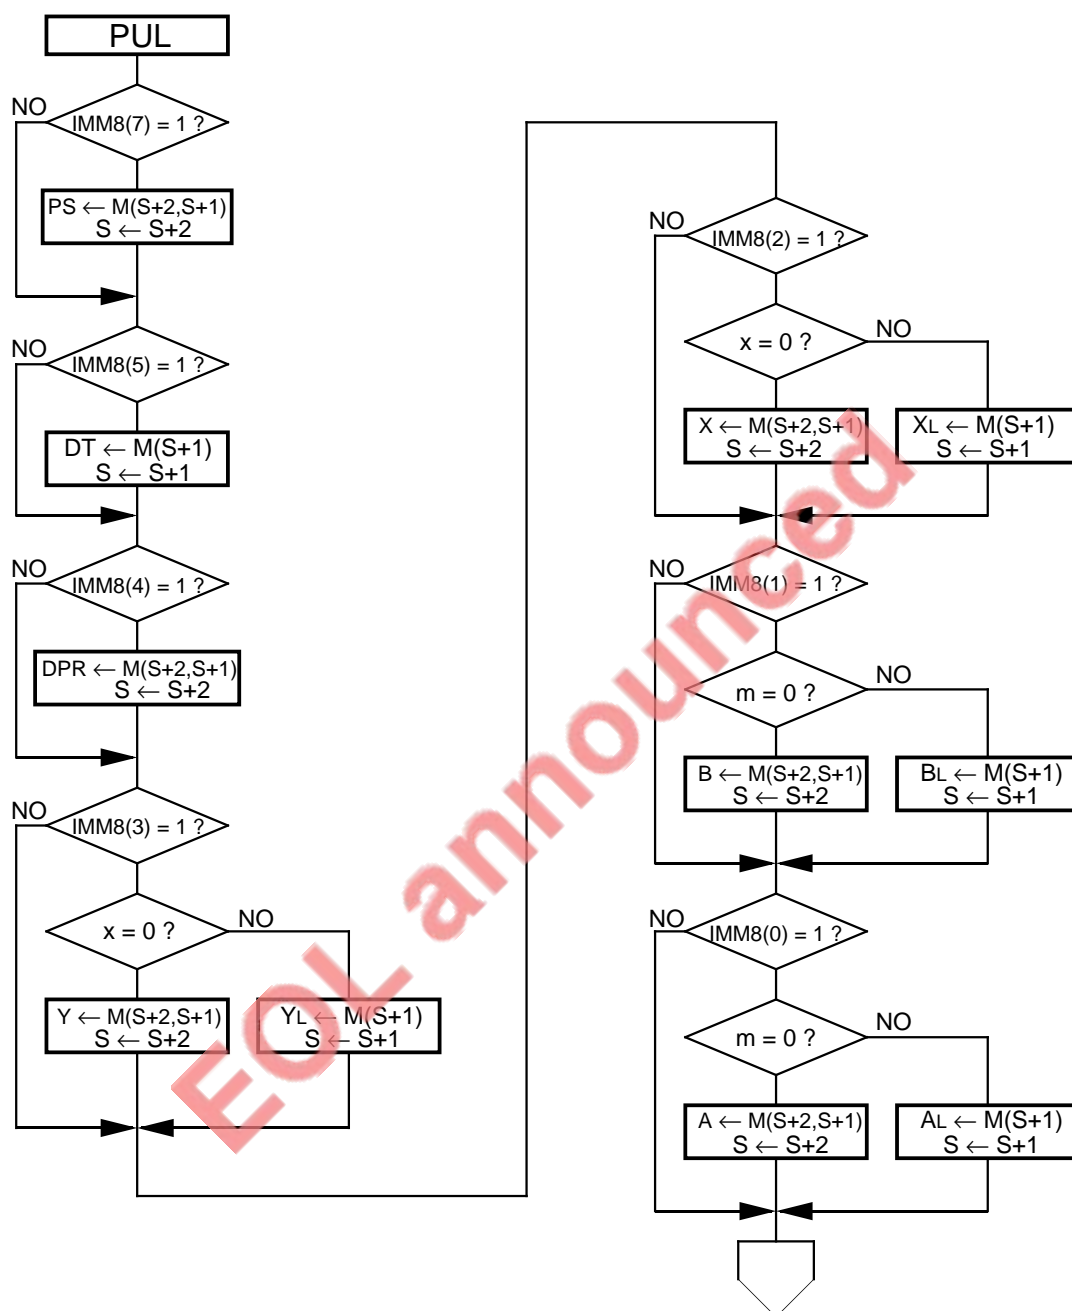

When restoring from stack, registers A and B are affected by the m flag in restored PS, and registers X and Y are affected by the x flag in restored PS. If PS is not restored, the registers are affected by the value of these flags just before instruction execution.

Status flags : When bit 7 of the instruction's second byte is 1, specifying that the program status register PS is to be restored, the status flags are restored to the values that had been restored from the stack. Otherwise, the status flags are not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Stack	PUL #nn	FB ₁₆ , nn	2	14+3xi ₁ +4xi ₂

(Note 1) To the cycles-count shown above, the values shown below are added depending on the registers being restored. The count is 14 cycles when no registers are restored. i₁ in above table represents the number of registers (chosen from A, B, X, Y, PS and DT) to be saved. i₂=1 if DPR is to be restored, and i₂=0 if DPR is not to be restored.

Register type	PS	DT	DPR	Y	X	B	A
Cycles-count	3	3	4	3	3	3	3

* IMM8 is an immediate value in 1-byte and inside of () specifies the contents of the bit at the value.

Function : n bits rotate to left

When m=0

When m=1

Description : The contents of the accumulator A are rotated to the left by n bits. The value of n is specified by the instruction's third byte (or third and fourth bytes when m=0).

Status flags : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Immediate	RLA #imm	89 ₁₆ , 49 ₁₆ , imm	3	6+i

i: Number of rotation

(Note 1) When the data length selection flag m is 0, the bytes-count increases by 1.

Function : Rotate to left

When $m=0$

When $m=1$

Description : The carry flag C is linked to the accumulator or memory, and the combined contents are rotated by 1 bit to the left.

Bit 0 of the accumulator or memory is loaded with the content of the carry flag C before execution of this instruction, and the carry flag C is loaded with the content of bit 15 (or bit 7 if the data length selection flag m is set to 1) of the accumulator or memory before execution of this instruction.

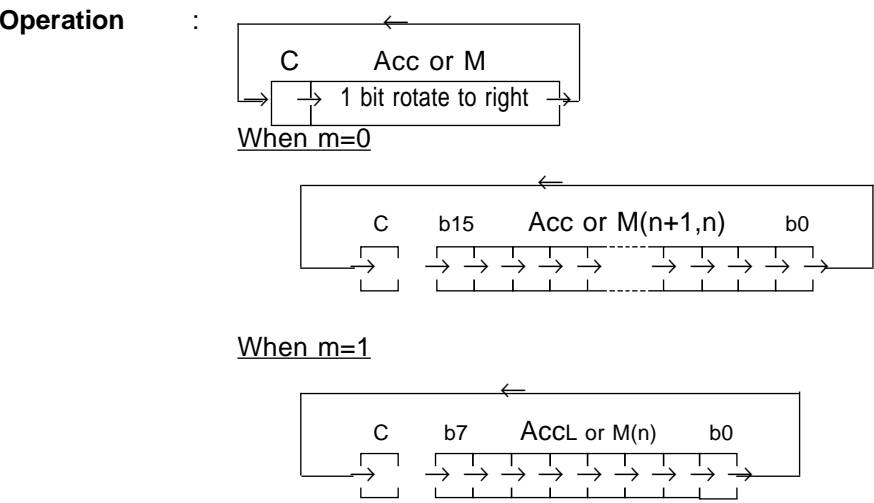

Status flags

- IPL : Not affected.
- N : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) of the operation result is 1. Otherwise, cleared to 0.
- V : Not affected.
- m : Not affected.
- x : Not affected.
- D : Not affected.
- I : Not affected.
- Z : Set to 1 when the result of operation is 0. Otherwise, cleared to 0.
- C : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) before execution of the instruction is 1. Otherwise, cleared to 0

Addressing mode	Syntax	Machine code	Bytes	Cycles
Accumulator	ROL A	2A ₁₆	1	2
Direct	ROL dd	26 ₁₆ , dd	2	7
Direct indexed X	ROL dd, X	36 ₁₆ , dd	2	7
Absolute	ROL mml	2E ₁₆ , ll, mm	3	7
Absolute indexed x	ROL mml, X	3E ₁₆ , ll, mm	3	8

(Note 1) The accumulator addressing mode's specification in this table applies when using the accumulator A. If using the accumulator B, replace "A" with "B". In this case, "42₁₆" is added at the beginning of the machine code, the bytes-count increases by 1 and the cycles-count increases by 2.

Function : Rotate to right

Description : The carry flag C is linked to the accumulator or memory, and the combined contents are shifted by 1 bit to the right.

Bit 15 (or bit 7 if the data length selection flag m is set to 1) of the accumulator or memory is loaded with the content of the carry flag C, and the carry flag C is loaded with the content of bit 0 of the accumulator or memory before execution of this instruction.

Status flags

- IPL : Not affected.
- N : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) of the operation result is 1. Otherwise, cleared to 0.
- V : Not affected.
- m : Not affected.
- x : Not affected.
- D : Not affected.
- I : Not affected.
- Z : Set to 1 when the result of operation is 0. Otherwise, cleared to 0.
- C : Set to 1 when bit 0 before execution of the instruction is 1. Otherwise, cleared to 0.

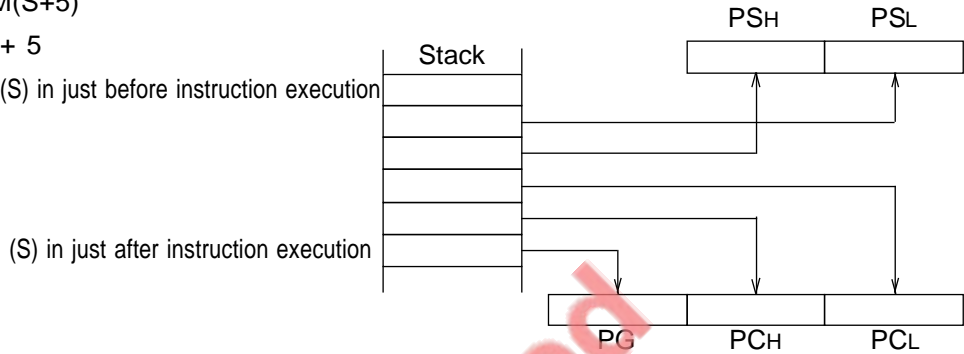

Addressing mode	Syntax	Machine code	Bytes	Cycles
Accumulator	ROR A	6A ₁₆	1	2
Direct	ROR dd	66 ₁₆ , dd	2	7
Direct indexed X	ROR dd, X	76 ₁₆ , dd	2	7
Absolute	ROR mmll	6E ₁₆ , ll, mm	3	7
Absolute indexed X	ROR mmll, X	7E ₁₆ , ll, mm	3	8

(Note 1) The accumulator addressing mode's specification in this table applies when using the accumulator A. If using the accumulator B, replace "A" with "B". In this case, "42₁₆" is added at the beginning of the machine code, the bytes-count increases by 1 and the cycles-count increases by 2.

Function : Return from subroutine

Operation : PG, PC, PS ← Stack (Saved content when interrupt occurred)

```
PS ← M(S+2, S+1)
PC ← M(S+4, S+3)
PG ← M(S+5)
S ← S + 5
```

Description : The contents of the processor status register PS, program counter PC, and program bank register PG, which are saved on the stack when the last interrupt was accepted, are restored these registers.

Status flags : Restored according to the values that had been on the stack.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Implied	RTI	40 ₁₆	1	11

Function : Return from subroutine

Operation : PG, PC ← Stack (Subroutine long return address)

PC ← M(S+2, S+1)
PG ← M(S+3)
S ← S + 3

Description : The program counter PC and program bank register PG are restored according to the state previously saved on the stack.

Status flags : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Implied	RTL	6B ₁₆	1	8

Function : Return from subroutine

Operation : $PC \leftarrow \text{Stack (Subroutine return address)}$

Description : The program counter PC is restored according to the state previously saved on the stack. The contents of PG is added 1 when this instruction is at topmost address (XXXXFF₁₆) of a bank.

Status flags : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Implied	RTS	60 ₁₆	1	5

Function : Subtract with carry

Operation : $\text{Acc} \leftarrow \text{Acc} - M - \bar{C}$
 When $m=0$

When $m=1$

Description : Subtracts the contents of memory and the 1's complements of carry flag from the contents of the accumulator, and places the result in the accumulator. Executed as a binary subtraction if the decimal operation mode flag D is set to 0. Executed as a decimal subtraction if the decimal operation mode flag D is set to 1.

Status flags

- IPL : Not affected.
- N : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) of the operation result is 1. Otherwise, cleared to 0. Meaningless for decimal subtraction.
- V : Set to 1 when binary subtraction of signed data results in a value outside the range of -32768 to +32767 (-128 to +127 if the data length selection flag m is set to 1). Otherwise, cleared to 0. Meaningless for decimal subtraction.
- m : Not affected.
- x : Not affected.
- D : Not affected.
- I : Not affected.
- Z : Set to 1 when the result of operation is 0. Otherwise, cleared to 0.
- C : Set to 1 when the result of operation is equal to or larger than 0. Otherwise, cleared to 0, and a borrow is indicated.

Function : Clock control

Operation : Stop the CPU clock

Description : The WIT instruction stops the internal clock but not the oscillation of the oscillation circuit is not stopped. To restart the internal clock, either an interrupt or reset must be executed.

Status flags : Not affected.

Addressing mode	Syntax	Machine code	Bytes	Cycles
Implied	WIT	CB ₁₆	1	3

EOL announced

Function : Exchange

Operation : $A \leftrightarrow B$

When m=0

When m=1

Description : Swaps the contents of the accumulators A and B.

Status flags

- IPL : Not affected.
- N : Set to 1 when bit 15 (or bit 7 if the data length selection flag m is set to 1) of the accumulator A after the operation is 1. Otherwise, cleared to 0.
- V : Not affected.
- m : Not affected.
- x : Not affected.
- D : Not affected.
- I : Not affected.
- Z : Set to 1 when the contents of the accumulator A is cleared to 0 by the operation. Otherwise, cleared to 0.
- C : Not affected.

INSTRUCTIONS

4.3 Notes for programming

4.3 Notes for Programming

Take care of the following when programming with the 7700 Family.

- (1) The stack pointer S is undefined immediately after the reset is commanded. Always set the initial value.

Example) **LDX #27FH**
 TXS

- (2) The program bank register PG and the data bank register DT are disabled under the single chip mode. Do not set value other than "00₁₆" here.

- (3) When "1" is set in the D-flag for decimal operation:

The C-flag alone is effective in the ADC instruction, while the Z, N, and V flags are disabled. The C and Z flags alone are effective in the SBC instruction, while the N and V flags are disabled. (Decimal operation can be done in the ADC and the SBC instructions alone.)

- (4) Using the 16-bit immediate data with "1" (data length : 8 bits) in the data length selection flag m, or using the 8-bit immediate data with "0" (data length : 16 bits) in flag m, will cause the program run-away. The same rule is applied to the index register length selection flag x. Take care of the condition of these flags when coding the program.

- (5) The 7700 Family can prefetch the instructions using the 3-byte instruction queue buffer. Keep in mind when creating the timer with the software, that the number of cycles shown in the list of machine language instructions is the minimum value. (Also see Chapter 5.)

- (6) When value other than "00₁₆" is set in the lower order 8 bits of the direct page register DPR (DPR_L), the processing time will become 1 machine cycle longer than when "00₁₆" is set.

- (7) The processing speed will deteriorate if a 16-bit data will be accessed from an odd address. Place the 16-bit data from an even address if the processing speed is important.

- (8) The N and Z flags will change by execution of the PLA instruction, but the contents of the processor status register will not change if the accumulator A alone is recovered by the PUL instruction.

- (9) The program bank register PG can be saved into the stack by setting "1" in bit 6 of the operation by the PSH instruction. However, the PG cannot be recovered by the PUL instruction.

- (10) The code in the second byte of the BRK instruction will not affect the CPU.

CHAPTER 5

INSTRUCTION EXECUTION SEQUENCE

5.1 Change of the CPU basic clock ϕ_{CPU}

5.2 Instruction execution sequence

INSTRUCTION EXECUTION SEQUENCE

5.1 Change of the CPU basic clock ϕ_{CPU}

The basic clock of the 7700 Family central processing unit (CPU) is the internal clock ϕ (divided by 2 of the oscillation frequency $f(X_{IN})$). The basic clock of the bus is an \bar{E} derived from the internal clock ϕ , so data exchange between the CPU and the internal bus is done via the bus interface unit (BIU). The frequency of \bar{E} is normally divided by 2 of the internal clock ϕ , but it becomes divided by 3 or 4 of ϕ , when accessing external memory while the wait is enabled by the wait bit (Note).

Note : The frequency of \bar{E} is depend on the product. Therefore, refer to an user's manual or a data sheet (or a data book) to confirm it.

5.1 Change of the CPU Basic Clock ϕ_{CPU}

When the bus interface unit is not ready, the CPU extends the basic clock to synchronize with the bus, and waits till it is ready. As the CPU basic clock waits owing to some conditions, this clock will be called ϕ_{CPU} to be distinguished from the clock ϕ . The following are the cases in which the ϕ_{CPU} waits.

Causes for the ϕ_{CPU} to wait

<Cause 1>

When the CPU requests operation codes and operands, but the operation codes and operands in the instruction queue buffer did not reach the necessary number.

<Cause 2>

When the CPU tried to access data, but the bus interface unit was using the bus for fetching some data into the instruction queue buffer or writing data.

<Cause 3>

When the bus interface unit was reading data from the internal/external memory or I/O, according to the request of the CPU.

In addition to the above, the following are also causes for the ϕ_{CPU} to be extended.

- When 16-bit data is accessed from odd address.
- When external memory 16-bit data is accessed while the BYTE terminal level is "H".
- When external memory is accessed with wait commanded by the wait bit.

The above conditions causes the execution time to differ each time, even with the same instruction and same addressing mode. Two example instructions are given in the next section to see the variation of the number of cycles according to the above conditions.

The "CPU execution sequence per addressing mode" of Chapter 6 is the CPU instruction execution sequences based on the ϕ_{CPU} . The number of cycles shown in "4.2 Instructions" and "Appendix 1 List of machine instructions" are the count for the shortest case, and cannot always be applied when calculating the actual cycles or the execution time of instructions.

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

5.2 Instruction Execution Sequence

This section describes how the instruction execution cycles change under various conditions.

- Example 1. ASL instruction Direct addressing mode
- Example 2. LDA instruction Direct indirect long addressing mode

Before observing the ϕ_{CPU} based CPU instruction execution sequence

The following table describes the ϕ_{CPU} based CPU instruction execution sequence symbols. The signals indicated in this execution sequence are all CPU internal signals, that show data exchange between the bus interface unit and the CPU. Accordingly, these signals cannot be observed from outside.

ϕ_{CPU} Based CPU Instruction Execution Sequence Symbols

Symbol	Description
ϕ_{CPU}	CPU basic clock
$A_{\text{P(CPU)}}$	Higher order 8 bits of the address (24 bits) of the program that the CPU is actually execution
$A_{\text{H}}A_{\text{L(CPU)}}$	Lower order 16 bits of the address (24 bits) of the program that the CPU is actually execution
$\text{DATA}_{\text{(CPU)}}$	Data information the CPU is processing
$\overline{\text{R/W}}_{\text{(CPU)}}$	Data read/write request to the data buffer in the bus interface unit
PG,PC	Contents of the program bank register (PG) and the program counter (PC)
AD_{P}	Data indicating the address (higher order 8 bits)
$\text{AD}_{\text{H}},\text{AD}_{\text{L}}$	Data indicating the address (lower order 16 bits)
DPR_{H}	Contents of the higher order 8 bits of the direct page register
DPR_{L}	Contents of the lower order 8 bits of the direct page register (DPR _L = 0 in the examples)
D_{H}	Data to be fetched or written from the data buffer by the CPU (higher order 8 bits)
D_{L}	Data to be fetched or written from the data buffer by the CPU (lower order 8 bits)
dd	Contents of the operand (DPR _L = 0 in examples 1 and 2, so dd represents the lower order 8 bits of the address)

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

Before observing the ϕ based instruction execution sequence

The ϕ based instruction execution sequence symbols are shown in the following table. The signals in this execution sequence indicates data exchange of the bus interface unit with the memory and I/O. The internal instruction execution sequence of the CPU can be guessed from these signals.

However, the ϕ_{CPU} and the number of data in the instruction queue buffer shown here cannot be observed from the outside.

ϕ Based Execution Sequence Symbols

Symbol	Description
ϕ	Basic operation clock of the microcomputer (divided by 2 of $f(XIN)$)
\bar{E}	Basic operation clock of the bus (divided by 2 of ϕ) * No wait
hh	Higher order 8 bits of the address where the bus interface unit is to access to (bank)
mm	Middle order 8 bits of the address where the bus interface unit is to access to
ll	Lower order 8 bits of the address where the bus interface unit is to access to
DPR	Contents of the direct page
DPRH	Contents of the higher order 8 bits of the direct page register
DPRL	Contents of the lower order 8 bits of the direct page register
OP1 OP2 OP3 :	Data to be fetched into the instruction queue buffer by the bus interface (Operation code or operand) The subscript represents the fetch sequence.
DL DH	Data to be fetched into the data buffer or data to be written into the memory by the bus interface unit
dd	Data obtained as the operand (The lower order 8 bits of the address are given in examples 1 and 2, because DPRL = 0.)
ADP	Higher order 8 bits of data that indicates the address (contents of the data address register)
ADH	Middle order 8 bits of data that indicates the address (contents of the data address register)
ADL	Lower order 8 bits of data that indicates the address (contents of the data address register)

The following are the cause of the " ϕ_{CPU} to queue" in the ϕ based instruction execution sequence.

Cause 1

When the CPU required operation codes and operands, but the number of operation codes and operands did not reach the requested number.

Cause 2

When the CPU tried to access data, but the bus interface was using the bus for fetching data into the instruction queue buffer or for writing data.

Cause 3

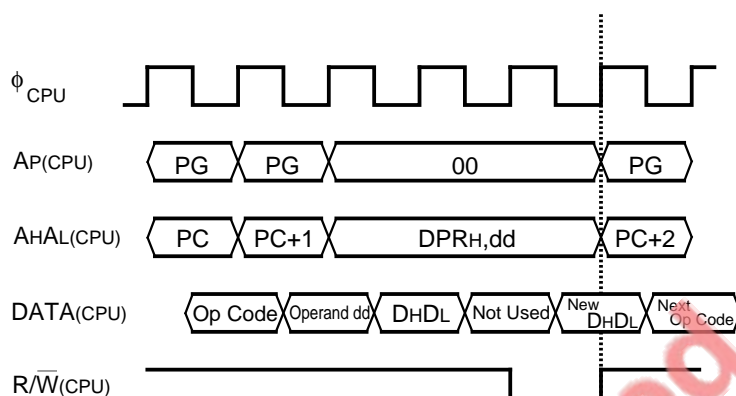

When the bus interface unit is reading data from the internal/external memory or I/O, etc., according to the request of the CPU.

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

Example 1. ASL instruction / direct addressing mode ($DPR_L = 00_{16}$)

ϕ_{CPU} based CPU instruction execution sequence

The following examples 1-1 to 1-6 are examples of the ϕ_{CPU} based instruction execution sequences under various conditions.

Example 1-1 When the instruction queue buffer is vacant

Example 1-2 When two data are in the instruction queue buffer

Example 1-3 When three data are in the instruction queue buffer

Example 1-4 When 16-bit data is accessed from odd address

Example 1-5 When external memory is accessed from the BYTE terminal using 8-bit external bus width

Example 1-6 When external memory is accessed with wait by the wait bit

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

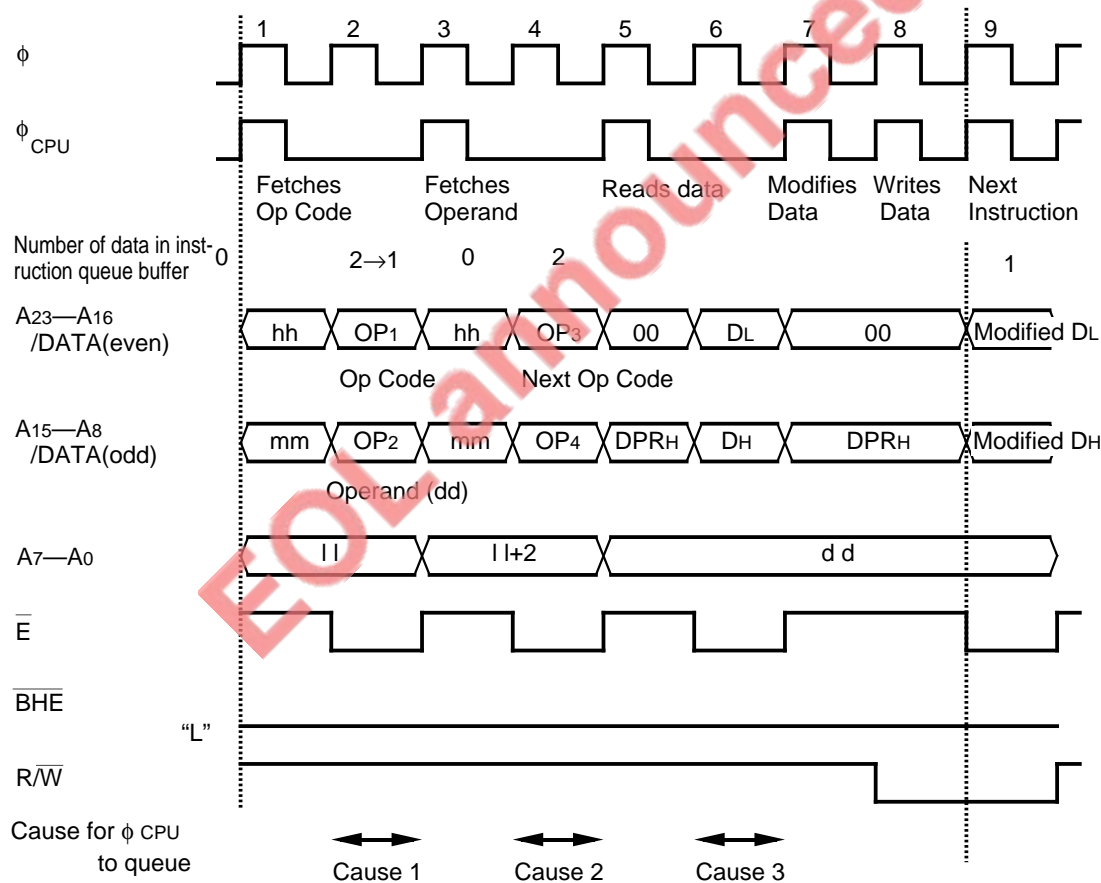

Example 1. ASL instruction / direct addressing mode (DPRL = 0016)

(Example 1-1) When the instruction queue buffer is vacant

Conditions

- Number of data in the instruction queue buffer 0
- ROM, RAM External memory is used (Note)
- Data length selection flag m "0" (16-bit length)
- BYTE terminal level "L" (External bus width is 16 bits)
- Contents of lower order bytes (PCL) of the program counter Even
- Contents of the operand (dd) Even

ϕ based execution sequence

Note. The operation when internal ROM and internal RAM are used, will be as shown above, regardless of the level of the BYTE terminal. However, the address/data bus, \overline{BHE} , R/W signal cannot be observed from outside, when the mode is single-chip mode.

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

Example 1. ASL instruction / direct addressing mode (DPRL = 0016)

Operation of the CPU and bus interface unit under various cycles

ϕ No.	CPU	Bus interface unit
1	(No fetching can be done, because there are no operation codes in the instruction queue buffer.)	Fetches the instruction, because instruction queue buffer is vacant and the CPU is not using the bus.
2	Fetches the operation code. 	Fetches 2-byte worth of data into the instruction queue buffer when \bar{E} becomes "L".
3	Fetches the operand.	Prefetches the instruction, because the instruction queue buffer is vacant and the CPU is not using the bus.
4	(Waits till the bus used by the bus interface unit becomes vacant.)	Fetches 2 bytes worth of data into the instruction queue buffer when \bar{E} becomes "L".
5	Waits for \bar{E} to become "L", to read data.	
6	Reads data when \bar{E} becomes "L".	
7	Modifies data.	
8	Writes data into the data buffer.	
9	Fetches the next operation code.	Writes the contents of the data buffer into the original address, when \bar{E} becomes "L".

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

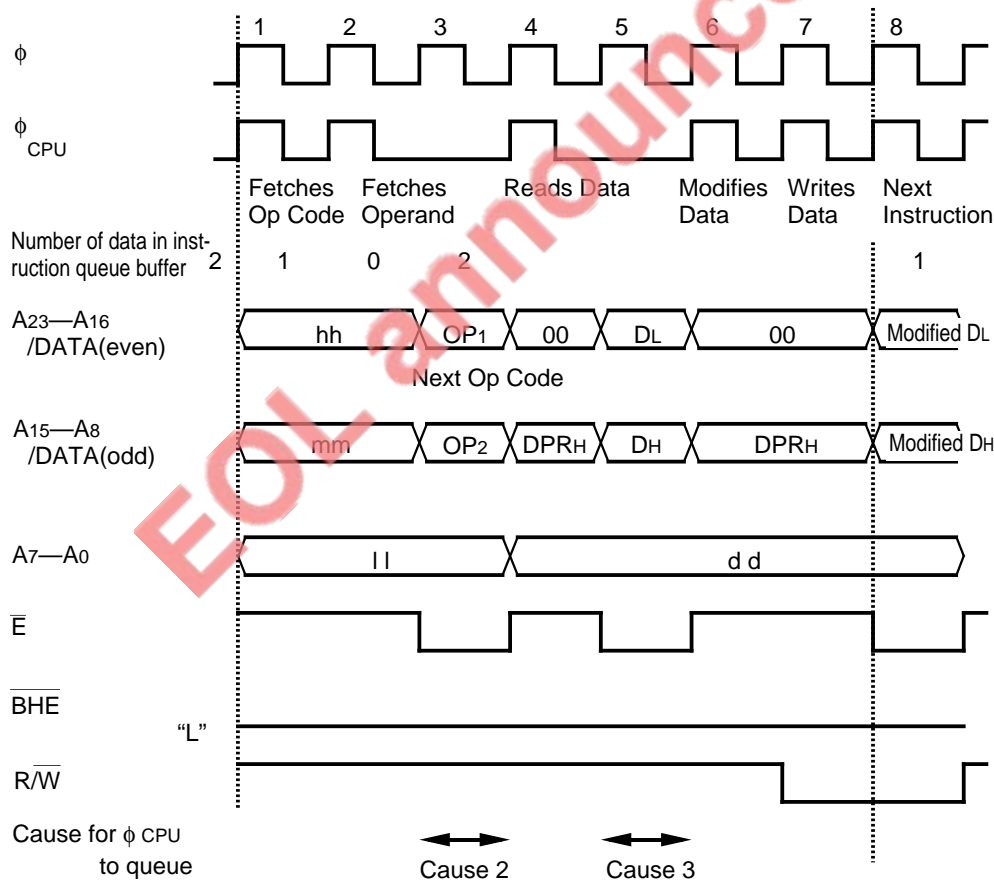

Example 1. ASL instruction / direct addressing mode (DPRL = 0016)

(Example 1-2) When two data are in the instruction queue buffer

Conditions

- Number of data in the instruction queue buffer 2
- ROM, RAM External memory is used (Note)
- Data length selection flag m "0" (16-bit length)
- BYTE terminal level "L" (External bus width is 16 bits)
- Contents of lower order bytes (PCL) of the program counter Even
- Contents of the operand (dd) Even

ϕ based execution sequence

Note. The operation when internal ROM and internal RAM are used, will be as shown above, regardless of the level of the BYTE terminal. However, the address/data bus, \overline{BHE} , $\overline{R/W}$ signal cannot be observed from outside, when the mode is single chip mode.

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

Example 1. ASL instruction / direct addressing mode (DPRL = 0016)

Operation of the CPU and bus interface unit under various cycles

ϕ No.	CPU	Bus interface unit
1	Fetches operation code.	
2	Fetches operand (dd).	Prefetches the instruction, because the instruction queue buffer is vacant and the CPU is not using the bus.
3	(Waits till the bus used by the bus interface unit becomes vacant.)	Fetches 2-byte worth of data into the instruction queue buffer when \bar{E} becomes "L".
4	Waits for \bar{E} to become "L", to read data.	
5	Reads data when \bar{E} becomes "L".	
6	Modifies data.	
7	Writes data into the data buffer.	
8	Fetches the next operation code.	Writes the contents of the data buffer into the original address, when \bar{E} becomes "L".

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

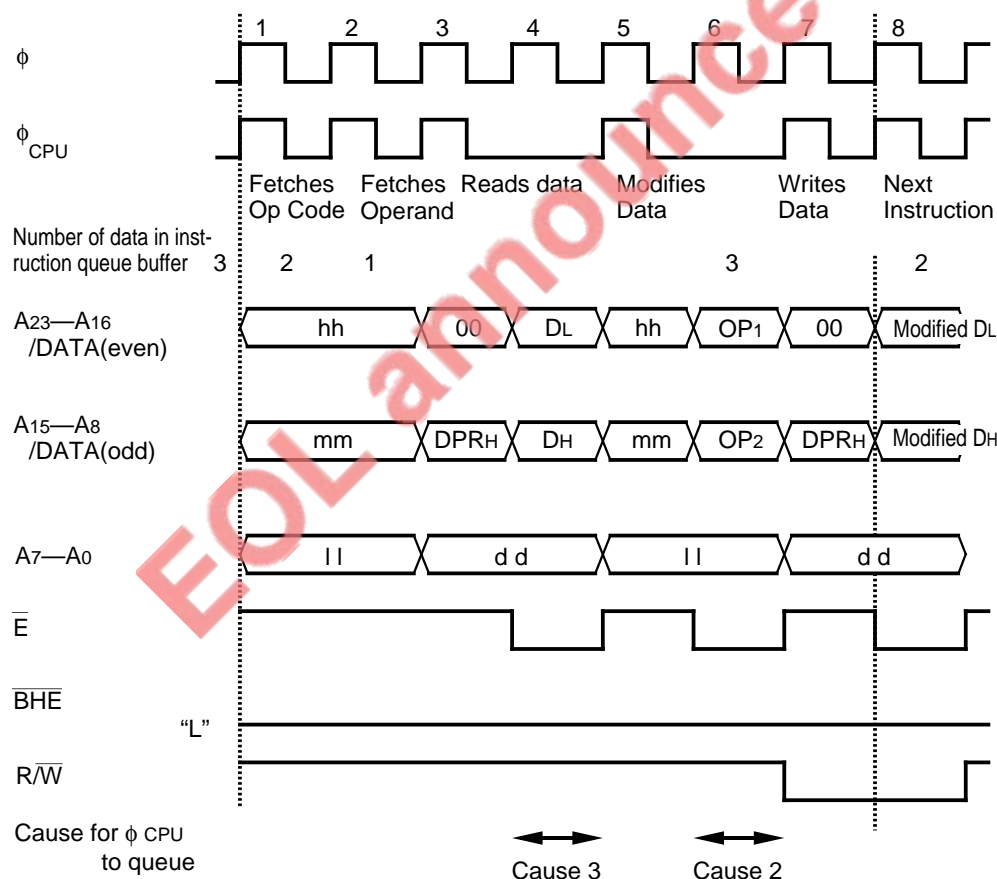

Example 1. ASL instruction / direct addressing mode (DPRL = 0016)

(Example 1-3) When three data are in the instruction queue buffer

Conditions

- Number of data in the instruction queue buffer 3
- ROM, RAM External memory is used (Note)
- Data length selection flag m "0" (16-bit length)
- BYTE terminal level "L" (External bus width is 16 bits)
- Contents of lower order bytes (PCL) of the program counter Even
- Contents of the operand (dd) Even

ϕ based execution sequence

Note. The operation when internal ROM and internal RAM are used, will be as shown above, regardless of the level of the BYTE terminal. However, the address/data bus, \overline{BHE} , R/\overline{W} signal cannot be observed from outside, when the mode is single chip mode.

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

Example 1. ASL instruction / direct addressing mode (DPRL = 0016)

Operation of the CPU and bus interface unit under various cycles

ϕ No.	CPU	Bus interface unit
1	Fetches operation code .	
2	Fetches operand (dd).	
3	Waits for \bar{E} to become "L", to read data.	
4	Reads data when \bar{E} becomes "L".	
5	Modifies data.	Prefetches the instruction, because there are two vacant instruction queue buffers and the CPU is not using the bus.
6	(Waits till the bus used by the bus interface unit becomes vacant.)	Fetches 2-byte worth of data into the instruction queue buffer when \bar{E} becomes "L".
7	Writes data into the data buffer.	
8	Fetches the next operation code.	Writes the contents of the data buffer into the original address, as \bar{E} becomes "L".

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

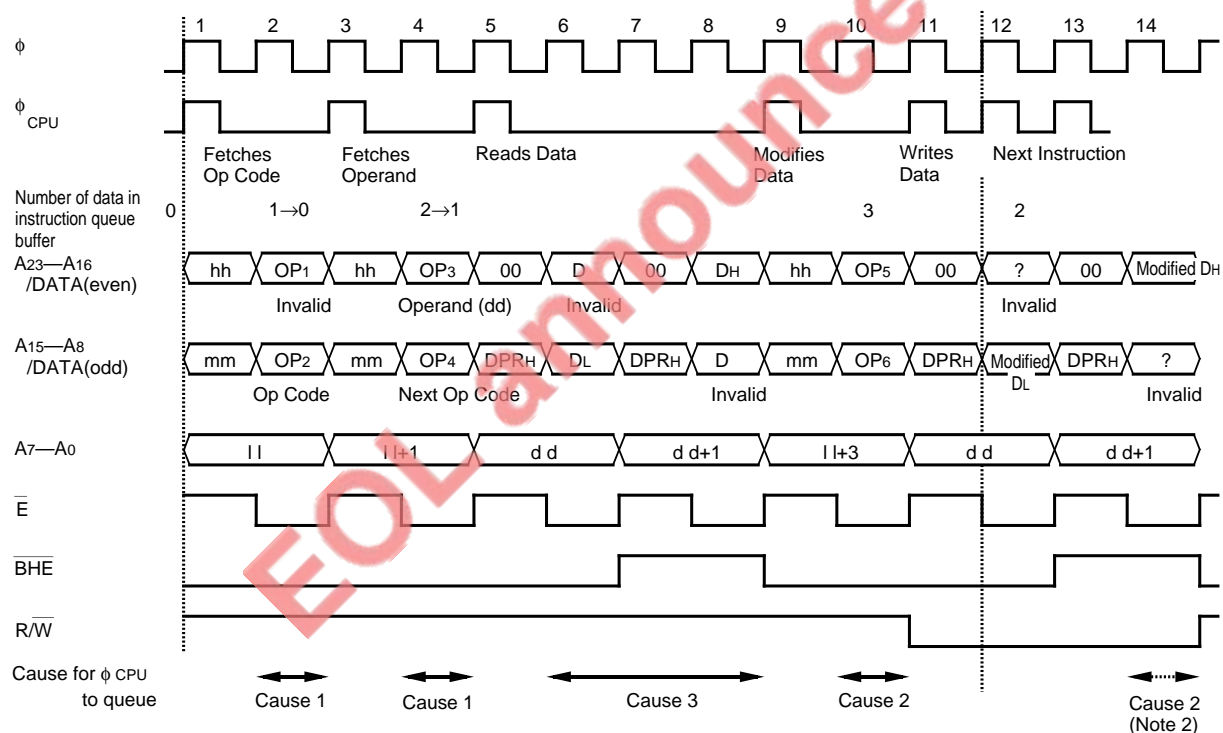

Example 1. ASL instruction / direct addressing mode (DPRL = 0016)

(Example 1-4) When 16-bit data is accessed from odd address

Conditions

- Number of data in the instruction queue buffer 0
- ROM, RAM External memory is used (Note 1)
- Data length selection flag m "0" (16-bit length)
- BYTE terminal level "L" (External bus width is 16 bits)
- Contents of lower order bytes (PCL) of the program counter Odd
- Contents of the operand (dd) Odd

ϕ based execution sequence

Note 1. The operation when internal ROM and internal RAM are used, will be as shown above, regardless of the level of the BYTE terminal. However, the address/data bus, \overline{BHE} , R/W signal cannot be observed from outside, when the mode is single chip mode.

Note 2. At the $\leftarrow \rightarrow$ part

* When the CPU does not use the bus, ϕ_{CPU} corresponds with ϕ .

* When the CPU uses the bus, the ϕ_{CPU} queues till the writing in the bus interface unit completes. (the ϕ_{14} cycle)

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

Example 1. ASL instruction / direct addressing mode (DPRL = 0016)

Operation of the CPU and bus interface unit under various cycles

ϕ No.	CPU	Bus interface unit
1	(No fetching can be done, because there are no operation codes in the instruction queue buffer.)	Fetches the instruction, because instruction queue buffer is vacant and the CPU is not using the bus.
2	Fetches operation code. 	Fetches 1 odd address byte worth of data into the instruction queue buffer, when \bar{E} becomes "L".
3	(No fetching can be done, because there are no operands in the instruction queue buffer.)	Fetches the instruction, because instruction queue buffer is vacant and the CPU is not using the bus.
4	Fetches operand (dd). 	Fetches 2-byte worth of data into the instruction queue buffer when \bar{E} becomes "L".
5	Waits for \bar{E} to become "L", to read data.	
6	Reads data in the odd addresses (DL) alone into the data buffer when \bar{E} becomes "L".	
7	Waits for \bar{E} to become "L", to read data.	
8	Reads data in the even addresses (DH) alone into the data buffer when \bar{E} becomes "L".	
9	Modifies data.	Prefetches the instruction, because there are two vacant positions in the instruction queue buffer, and the CPU is not using the bus.
10	(Waits till the bus used by the bus interface unit becomes vacant.)	Fetches 2 bytes worth of data into the instruction queue buffer, when \bar{E} becomes "L".
11	Writes data into the data buffer.	Waits till \bar{E} becomes "L" to write data.
12	Fetches the next operation code.	Writes the contents of the data buffer (DL) into the original address (odd address), when \bar{E} becomes "L".
13	?	Waits till \bar{E} becomes "L" to write data.
14	?	Writes the contents of the data buffer (DH) into the original address (even address), when \bar{E} becomes "L".

When internal ROM or BYTE terminal level "L" external memory is used as the program memory, the instruction is fetched into the instruction queue buffer normally in 2-byte (word) unit of sequential even and odd addresses in this order. However, when the instruction must be fetched from odd address like after execution of the JMP instruction, the 1-byte of the first odd address alone is fetched into the instruction queue buffer ($\phi 2$ cycle), and the later instructions are fetched into the instruction queue buffer in 2-byte units ($\phi 4$, $\phi 10$ cycle).

The bus interface unit automatically selects whether to fetch one word or to fetch the 1 byte of odd address alone. The operation status can be observed from outside, according to the output of the \bar{BHE} terminal and the address bus signal A_0 , as long as the mode is not single-chip mode.

- When one word is fetched
The output from both the \bar{BHE} terminal and the address bus A_0 are at the "L" level.
- When 1 byte of odd address alone is fetched
The output from the \bar{BHE} terminal is "L", while the output from address bus A_0 is "H".

When internal RAM and external memory at BYTE terminal level "L" are used as the data memory, with data length selection flag $m=0$, both data read and write are normally done in 2-byte units of even and odd addresses, in this sequence. However, access can also be done when the word data is defined from an odd address. In other words, "H" is output first from address bus A_0 and then "L" from the \bar{BHE} terminal to access to odd address alone. Next, "L" is output from A_0 , and "H" from the \bar{BHE} terminal to access to the even address ($\phi 5$ to $\phi 8$, $\phi 11$ to $\phi 14$ cycle).

INSTRUCTION EXECUTION SEQUENCE

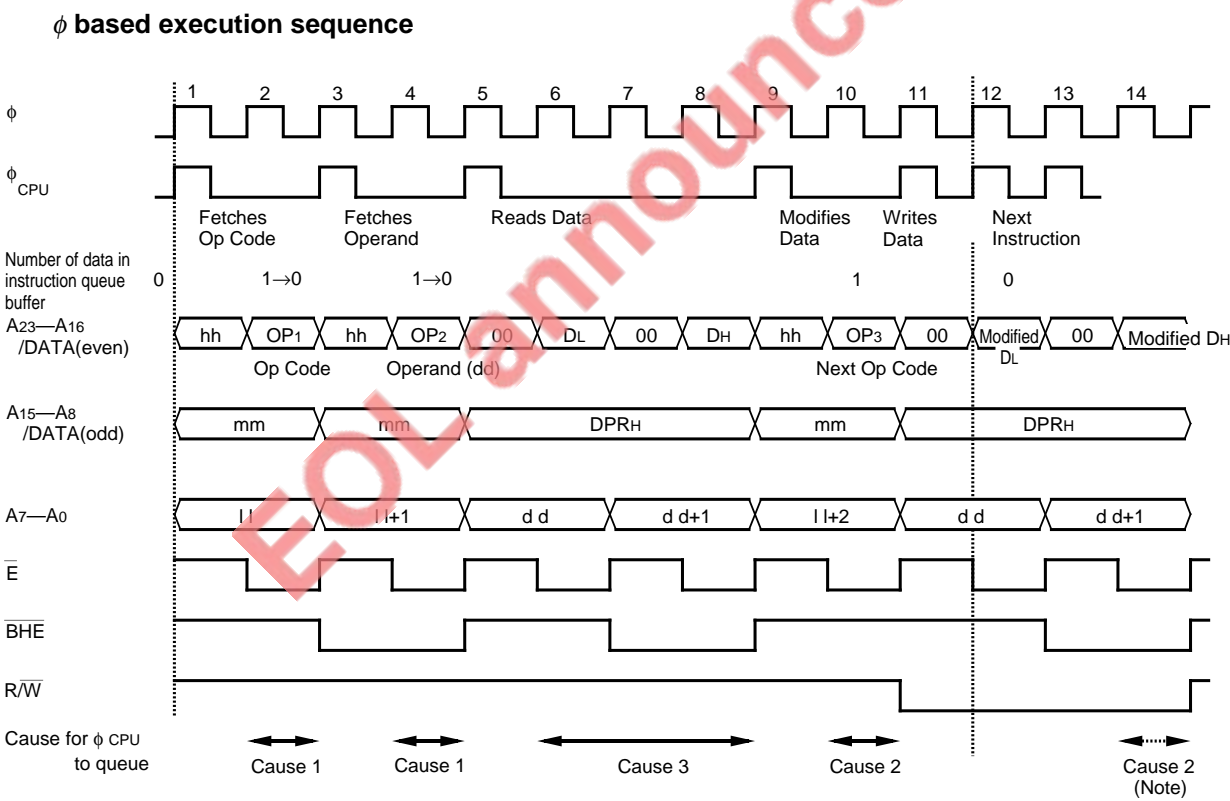

5.2 Instruction execution sequence

Example 1. ASL instruction / direct addressing mode (DPRL = 0016)

(Example 1-5) When external memory is accessed from the BYTE terminal using 8-bit external bus width

Conditions

- Number of data in the instruction queue buffer 0
- ROM, RAM External memory is used
- Data length selection flag m "0" (16-bit length)
- BYTE terminal level "H" (External bus width is 8 bits)

Note. At the \longleftrightarrow part

- * When the CPU does not use the bus, ϕ_{CPU} corresponds with ϕ .
- * When the CPU uses the bus, the ϕ_{CPU} queues till the writing in the bus interface unit completes. (the ϕ_{13} to ϕ_{14} cycle)

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

Example 1. ASL instruction / direct addressing mode (DPRL = 0016)

Operation of the CPU and bus interface unit under various cycles

ϕ No.	CPU	Bus interface unit
1	(No fetching can be done, because there are no operation codes in the instruction queue buffer.)	Fetches the instruction, because the instruction queue buffer is vacant and the CPU is not using the bus.
2	Fetches operation code. 	Fetches 1 odd address byte worth of data into the instruction queue buffer when \bar{E} becomes "L".
3	(No fetching can be done, because there are no operands in the instruction queue buffer.)	Fetches the instruction, because instruction queue buffer is vacant and the CPU is not using the bus.
4	Fetches operand (dd). 	Fetches 1-byte worth of data into the instruction queue buffer when \bar{E} becomes "L".
5	Waits for \bar{E} to become "L", to read data.	
6	Reads data (DL) into the data buffer when \bar{E} becomes "L".	
7	Waits for \bar{E} to become "L", to read data.	
8	Reads data (DH) alone into the data buffer when \bar{E} becomes "L".	
9	Modifies data.	Prefetches the instruction, because there are two vacant positions in the instruction queue buffer, and the CPU is not using the bus.
10	(Waits till the bus used by the bus interface unit is vacant.)	Fetches 1 byte worth of data into the instruction queue buffer when \bar{E} becomes "L".
11	Writes data into the data buffer.	Waits till \bar{E} becomes "L" to write data.
12	Fetches the next operation code.	Writes the contents of the data buffer (DL) into the original address (odd address), when \bar{E} becomes "L".
13	?	Waits till \bar{E} becomes "L" to write data.
14	?	Writes the contents of the data buffer (DH) into the original address (even address), when \bar{E} becomes "L".

The external bus width becomes 8 bits when the "H" level is applied to the BYTE terminal. (The width of the internal bus is 16 bits, regardless of the level of the BYTE terminal.) When external ROM is used under this mode, the instruction can only be fetched byte by byte. ($\phi 2$, $\phi 4$, $\phi 10$ cycle) When external RAM is used, the data can likewise only be handled byte by byte. Accordingly, when data length selection flag $m = 0$ is selected, it takes time worth 2 cycles of the enable output \bar{E} for data read and write. ($\phi 5$ to $\phi 8$, $\phi 11$ to $\phi 14$ cycle)

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

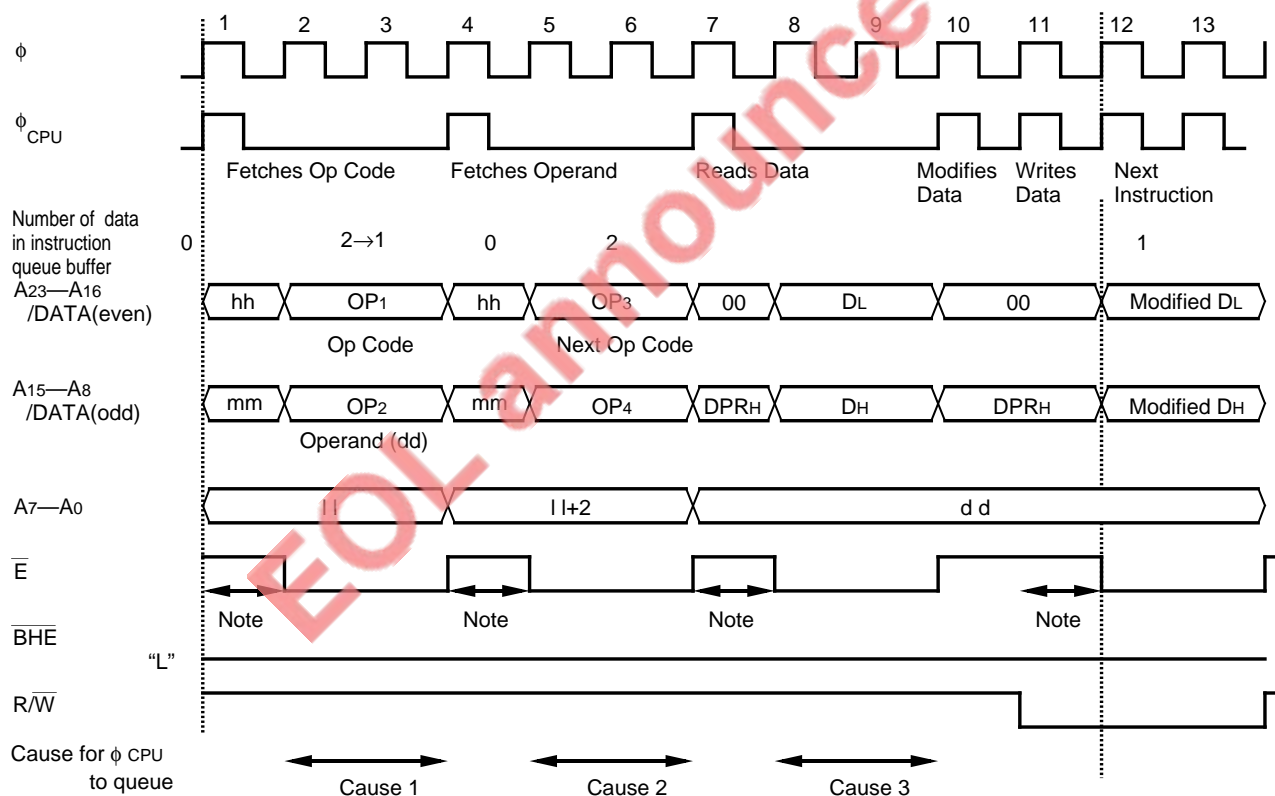

Example 1. ASL instruction / direct addressing mode (DPRL = 0016)

(Example 1-6) When external memory is accessed with wait by the wait bit

Conditions

- Number of data in the instruction queue buffer 0
- ROM, RAM External memory is used
- Data length selection flag m "0" (16-bit length)
- BYTE terminal level "L" (External bus width is 16 bits)
- Contents of lower order bytes (PCL) of the program counter Even
- Contents of the operand (dd) Even

ϕ based execution sequence

Note: This figure shows the case of the bus cycle becoming 3 cycles of ϕ . If the bus cycle becomes 4 cycles of ϕ by wait, the "H" width of \bar{E} (\longleftrightarrow) becomes 2 cycles. Therefore, the ASL instruction execution time is extended by 4 cycles from the above case.

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

Example 1. ASL instruction / direct addressing mode (DPRL = 0016)

Operation of the CPU and bus interface unit under various cycles

ϕ No.	CPU	Bus interface unit
1	(No fetching can be done, because there are no operation codes in the instruction queue buffer.)	Fetches the instruction, because instruction queue buffer is vacant and the CPU is not using the bus.
2 3	Fetches the operation code ←	Fetches 2 bytes worth of data into the instruction queue buffer when \bar{E} becomes "L".
4	Fetches operand (dd).	Prefetches the instruction because the instruction queue buffer is vacant and the CPU is not using the bus.
5 6	(Waits till the bus used by the bus interface unit becomes vacant.)	Fetches 2 bytes worth of data into the instruction queue buffer when becomes "L".
7	Waits till \bar{E} becomes "L" to write data.	
8 9	Reads data when \bar{E} becomes "L".	
10	Modifies data.	
11	Writes data into the data buffer.	
12	Fetches the next operation code.	
13	?	Writes the contents of the data buffer into the original address (odd address), when \bar{E} becomes "L".

The conditions are the same as the Example 1-1, except when wait is commanded by the wait bit . When accessing to the external memory, the "L" width of enable output \bar{E} is extended by 1 cycle of ϕ when compared to the case of no wait. Therefore, the ϕ CPU wait interval is also extended by 1 cycle ($\phi 2$ to $\phi 3$, $\phi 5$ to $\phi 6$, $\phi 8$ to $\phi 9$ cycle).

If the bus cycle becomes 4 cycles, the ϕ CPU wait interval is also extended by 2 cycles of ϕ because the "H" and "L" width extended by 1 cycle from the case no wait.

INSTRUCTION EXECUTION SEQUENCE

EOL announced

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

Example 2. LDA instruction / Direct indirect long addressing mode ($DPR_L = 00_{16}$)

ϕ_{CPU} based CPU instruction execution sequence

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

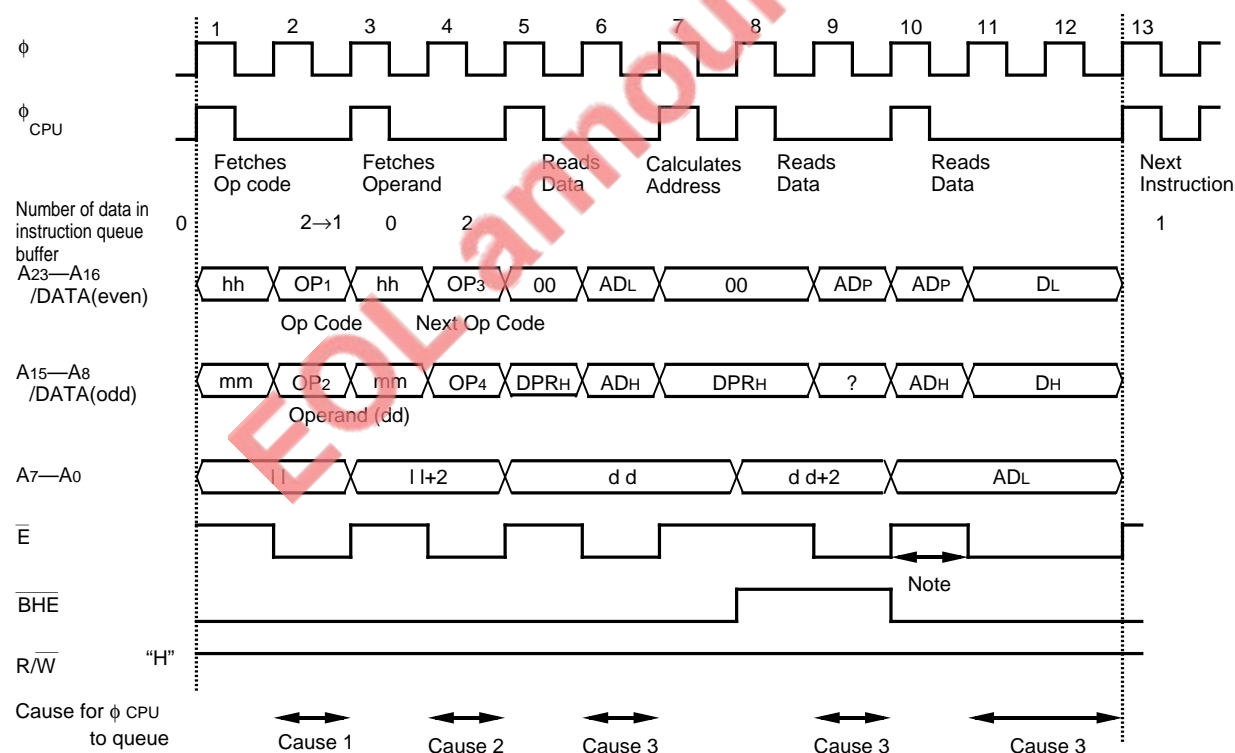

Example 2. LDA instruction / Direct indirect long addressing mode (DPRL = 0016)

(Example 2-1) When the internal as well as the external memories are used together while wait is commanded by the wait bit.

Conditions

- Number of data in the instruction queue buffer 0
- Bank 0 Internal ROM, RAM are used
Bank 1 and after External memory is used
- Data length selection flag m "0" (16-bit length)
- BYTE terminal level "L" (External bus width is 16 bits)
- Contents of lower order bytes (PCL) of the program counter Even
- Contents of the operand (dd) Even
- Data indicated by the address ADL Even
ADP 1 or more (bank 1 and after)

ϕ based execution sequence

Note: This figure shows the case of the bus cycle becomes as 3 cycles of ϕ . If the bus cycle becomes 4 cycles of ϕ by wait, the "H" width of \overline{E} (\longleftrightarrow) becomes as 2 cycles.

INSTRUCTION EXECUTION SEQUENCE

5.2 Instruction execution sequence

Example 2. LDA instruction / Direct indirect long addressing mode (DPRL = 0016)

Operation of the CPU and bus interface unit under various cycles

ϕ No.	CPU	Bus interface unit
1	(No fetching can be done, because there are no operation codes in the instruction queue buffer.)	Fetches the instruction, because instruction queue buffer is vacant and the CPU is not using the bus.
2	Fetches the operation code .	Fetches 2 bytes worth of data into the instruction queue buffer when \bar{E} becomes "L".
3	Fetches operand (dd).	Prefetches the instruction because the instruction queue buffer is vacant and the CPU is not using the bus.
4	(Waits till the bus used by the bus interface unit becomes vacant.)	Fetches 2 bytes worth of data into the instruction queue buffer when \bar{E} becomes "L".
5	Waits for \bar{E} to becomes "L", to read data (ADH, ADL) indicated by the address obtained by adding the contents of the operand (dd) and the DPRL.	
6	Reads data when \bar{E} becomes "L".	
7		Calculated address.
8	Waits for \bar{E} to become "L", to read data (ADP).	
9	Reads data when \bar{E} becomes "L".	
10	Waits for \bar{E} to become "L", to read the data (DH, DL) at the address specified by ADP, ADH, ADL.	
11	Reads data when \bar{E} becomes "L".	
12		

The above is the case when bank 1 and after are used by the external memory under the memory expansion mode. The currently executed program is in bank 0. The contents of the lower order bytes of the direct page register DPRL is "0016", so the direct pages are all in bank 0. The access to the outside ($\phi 10$ to $\phi 12$ cycle) alone is affected by the wait bit, and access to the internal memory is not affected by the bit.

CHAPTER 6

CPU INSTRUCTION EXECUTION SEQUENCE FOR EACH ADDRESSING MODE

EOL announced

CPU INSTRUCTION EXECUTION SEQUENCE FOR EACH ADDRESSING MODES

The following are the CPU instruction execution sequences for each addressing mode. The execution sequences shown here describe the internal operation of the CPU. Therefore, the signals are all CPU internal signals, and cannot be observed from outside. The CPU internal operation, the actual execution time, and the relation between signals that can be externally checked are described in Chapter 4 "Instruction Execution Sequence".

The following are the signals and the symbols indicating the contents.

Symbol	Description
ϕ_{CPU}	CPU basic cycle
$AP_{(\text{CPU})}$	Higher order 8 bits of the CPU internal address bus.
$AHAL_{(\text{CPU})}$	Lower order 16 bits of the CPU internal address bus.
PG	Contents of the program bank register.
PC	Contents of the program counter.
	Others are data that indicates the address obtained as result of address calculation.
$DATA_{(\text{CPU})}$	The CPU internal data bus. The signal is output with a half-cycle delay from the CPU internal address bus. The operation codes and the operands are fetched from the instruction buffer. They are not directly fetched from the memory indicated by the PG and PC of this cycle.
$R/\overline{W}_{(\text{CPU})}$	Becomes "L" when the CPU writes data into the data buffer of the bus interface unit.

The accumulator used in the above instructions in the CPU instruction execution sequence is accumulator A. When accumulator B is used, the execution cycle will have the two cycles of a "42₁₆" that indicates accumulator B, and an internal processing cycle added at the front. (See the figure in the next page.)

The number of ϕ_{CPU} cycles differs in the addressing mode that uses the direct page register, according to whether the lower order 8 bits (DPR_L) are "00₁₆". The number of cycles when $DPR_L = 00_{16}$ is 1 cycle (address calculation cycle) less than when $DPR_L \neq 00_{16}$.

The number of cycles differs in the PSH and PUL instructions according to the number and type of registers placed in (taken out of) the stack.

The number of cycles differs in the block transmission instruction (MVN, MVP), according to the number of the data transmitted.

Note. The instructions with the mark "*" can be used in the 7750 Series only.

APPENDIX.1 Machine Instructions

EOL announced

APPENDIX

APPENDIX.1 Machine Instructions

The number of cycles shown in the table is described in case of the fastest mode for each instruction. The number of cycles shown in the table is calculated for $DPR_L=0$. The number of cycles in the addressing mode concerning the DPR when $DPR_L \neq 0$ must be incremented by 1. The number of cycles shown in the table differs according to the bytes fetched into the instruction queue buffer, or according to whether the memory read/write address is odd or even. It also differs when the external region memory is accessed by $BYTE="H"$.

Note 1. The operation code at the upper row is used for accumulator A, and the operation at the lower row is used for accumulator B.

Note 2. When setting flag $m=0$ to handle the data as 16-bit data in the immediate addressing mode, the number of bytes increments by 1.

Note 3. The number of cycles increments by 2 when branching.

Note 4. The operation code on the upper row is used for branching in the range of $-128 \sim +127$, and the operation code on the lower row is used for branching in the range of $-32768 \sim +32767$.

Note 5. When handling 16-bit data with flag $m=0$, the byte in the table is incremented by 1.

Note 6.

Type of register	A	B	X	Y	DPR	DT	PG	PS
Number of cycles	2	2	2	2	2	1	1	2

The number of cycles corresponding to the register to be pushed are added. The number of cycles when no pushing is done is 12. i_1 indicates the number of registers among A, B, X, Y, DPR, and PS to be saved, while i_2 indicates the number of registers among DT and PG to be saved.

Note 7.

Type of register	A	B	X	Y	DPR	DT	PS
Number of cycles	3	3	3	3	4	3	3

The number of cycles corresponding to the register to be pulled are added. The number of cycles when no pulling is done is 14. i_1 indicates the number of registers among A, B, X, Y, DT, and PS to be restored, while $i_2=1$ when DPR is to be restored.

Note 8. The number of cycles is the case when the number of bytes to be transferred is even.

When the number of bytes to be transferred is odd, the number is calculated as;

$$7 + (i/2) \times 7 + 4$$

Note that, $(i/2)$ shows the integer part when i is divided by 2.

Note 9. The number of cycles is the case when the number of bytes to be transferred is even.

When the number of bytes to be transferred is odd, the number is calculated as;

$$9 + (i/2) \times 7 + 5$$

Note that, $(i/2)$ shows the integer part when i is divided by 2.

Note 10. The number of cycles is the case in the 16-bit \div 8-bit operation. The number of cycles is incremented by 16 for 32-bit \div 16-bit operation.

Note 11. The number of cycles is the case in the 8-bit \times 8-bit operation. The number of cycles is incremented by 8 for 16-bit \times 16-bit operation.

Note 12. When setting flag $x=0$ to handle the data as 16-bit data in the immediate addressing mode, the number of bytes increments by 1.

Note 13. When flag m is 0, the byte in the table is incremented by 1.

Note 14. The cycles-count in this table are for 8-bit \times 8-bit multiplications with the same sign. If the multiplier and multiplicand have different signs, three additional cycles are required. For 16-bit \times 16-bit multiplications, the cycles-count increases by 8.

Note 15. The cycles-count in this table are for 16-bit \div 8-bit operations. For 32-bit \div 16-bit operations, the cycles-count increases by 16.

APPENDIX

APPENDIX.1 Machine Instructions

Symbols in machine instructions table

Symbol	Description	Symbol	Description
IMP	Implied addressing mode	⊕	Exclusive OR
IMM	Immediate addressing mode	—	Negation
A	Accumulator addressing mode	↔	Movement to the arrow direction
DIR	Direct addressing mode	A _{CC}	Accumulator
DIR, b	Direct bit addressing mode	A _{COH}	Accumulator's upper 8 bits
DIR, X	Direct indexed X addressing mode	A _{COL}	Accumulator's lower 8 bits
DIR, Y	Direct indexed Y addressing mode	A	Accumulator A
(DIR)	Direct indirect addressing mode	A _H	Accumulator A's upper 8 bits
(DIR, X)	Direct indexed X indirect addressing mode	A _L	Accumulator A's lower 8 bits
(DIR), Y	Direct indirect indexed Y addressing mode	B	Accumulator B
L (DIR)	Direct indirect long addressing mode	B _H	Accumulator B's upper 8 bits
L (DIR), Y	Direct indirect long indexed Y addressing mode	B _L	Accumulator B's lower 8 bits
ABS	Absolute addressing mode	X	Index register X
ABS, b	Absolute bit addressing mode	X _H	Index register X's upper 8 bits
ABS, X	Absolute indexed X addressing mode	X _L	Index register X's lower 8 bits
ABS, Y	Absolute indexed Y addressing mode	Y	Index register Y
ABL	Absolute long addressing mode	Y _H	Index register Y's upper 8 bits
ABL, X	Absolute long indexed X addressing mode	Y _L	Index register Y's lower 8 bits
(ABS)	Absolute indirect addressing mode	S	Stack pointer
L (ABS)	Absolute indirect long addressing mode	PC	Program counter
(ABS, X)	Absolute indexed X indirect addressing mode	PC _H	Program counter's upper 8 bits
STK	Stack addressing mode	PC _L	Program counter's lower 8 bits
REL	Relative addressing mode	PG	Program bank register
DIR, b, REL	Direct bit relative addressing mode	DT	Data bank register
ABS, b, REL	Absolute bit relative addressing mode	DPR	Direct page register
SR	Stack pointer relative addressing mode	DPR _H	Direct page register's upper 8 bits
(SR), Y	Stack pointer relative indirect indexed Y addressing mode	DPR _L	Direct page register's lower 8 bits
BLK	Block transfer addressing mode	PS	Processor status register
C	Carry flag	PS _H	Processor status register's upper 8 bits
Z	Zero flag	PS _L	Processor status register's lower 8 bits
I	Interrupt disable flag	PS _b	Processor status register's b-th bit
D	Decimal operation mode flag	M(S)	Contents of memory at address indicated by stack pointer
x	Index register length selection flag	M _b	b-th memory location
m	Data length selection flag	AD _G	Value of 24-bit address's upper 8-bit (A ₂₃ ~A ₁₆)
V	Overflow flag	AD _H	Value of 24-bit address's middle 8-bit (A ₁₅ ~A ₈)
N	Negative flag	AD _L	Value of 24-bit address's lower 8-bit (A ₇ ~A ₀)
IPL	Processor interrupt priority level	op	Operation code
+	Addition	n	Number of cycle
—	Subtraction	#	Number of byte
*	Multiplication	i	Number of transfer byte or rotation
/	Division	i ₁ , i ₂	Number of registers pushed or pulled
^	Logical AND		
∨	Logical OR

Note 1. The code of each instruction first word is 8916.

Note 2. "*" shows the instructions can be used in 7750 Series.

APPENDIX

APPENDIX.1 Machine Instructions

Symbol	Function	Details	Addressing mode																														
			IMP		IMM		A		DIR		DIR,b		DIR,X		DIR,Y		(DIR)		(DIR,X)		(DIR),Y												
			op	n #	op	n #	op	n #	op	n #	op	n #	op	n #	op	n #	op	n #	op	n #	op	n #	op	n #									
ADC (Note 1,2)	$Acc,C \leftarrow Acc + M + C$	Adds the carry, the accumulator and the memory contents. The result is entered into the accumulator. When the D flag is "0", binary additions is done, and when the D flag is "1", decimal addition is done.				69	2	2				65	4	2				75	5	2				72	6	2	61	7	2	71	8	2	
						42	4	3				42	6	3				42	7	3				42	8	3	42	9	3	42	10	3	
						69						65						75						72			61			71			
AND (Note 1,2)	$Acc \leftarrow Acc \wedge M$	Obtains the logical product of the contents of the accumulator and the contents of the memory. The result is entered into the accumulator.				29	2	2				25	4	2				35	5	2				32	6	2	21	7	2	31	8	2	
						42	4	3				42	6	3				42	7	3				42	8	3	42	9	3	42	10	3	
						29						25						35						32			21			31			
ASL (Note 1)	$m=0$ $\boxed{C} \leftarrow \boxed{b_{15}} \dots \boxed{b_0} \rightarrow \boxed{C}$ $m=1$ $\boxed{C} \leftarrow \boxed{b_7} \dots \boxed{b_0} \rightarrow \boxed{C}$	Shifts the accumulator or the memory contents one bit to the left. "0" is entered into bit 0 of the accumulator or the memory. The contents of bit 15 (bit 7 when the m flag is "1") of the accumulator or memory before shift is entered into the C flag.							0A	2	1	06	7	2				16	7	2													
									42	4	2																						
									0A																								
ASR* (Note 1)	$m=0$ $\boxed{b_{15}} \dots \boxed{b_0} \rightarrow \boxed{C}$ $m=1$ $\boxed{b_7} \dots \boxed{b_0} \rightarrow \boxed{C}$	Shifts the accumulator or the memory contents one bit to the right. The bit 0 of the accumulator or memory is entered into the C flag. The contents of bit 15 (bit 7 when the m flag is "1") of the accumulator or memory before shift is entered into bit 15 (bit 7).							89	5	2	89	9	3				89	10	3													
									08			06						16															
									42	5	2																						
									08																								
BBC (Note 3,5)	$Mb=0?$	Tests the specified bit of the memory. Branches when all the contents of the specified bit is "0".																															
BBS (Note 3,5)	$Mb=1?$	Tests the specified bit of the memory. Branches when all the contents of the specified bit is "1".																															
BCC (Note 3)	$C=0?$	Branches when the contents of the C flag is "0".																															
BCS (Note 3)	$C=1?$	Branches when the contents of the C flag is "1".																															
BEQ (Note 3)	$Z=1?$	Branches when the contents of the Z flag is "1".																															
BMI (Note 3)	$N=1?$	Branches when the contents of the N flag is "1".																															
BNE (Note 3)	$Z=0?$	Branches when the contents of the Z flag is "0".																															
BPL (Note 3)	$N=0?$	Branches when the contents of the N flag is "0".																															
BRA (Note 4)	$PC \leftarrow PC \pm \text{offset}$ $PG \leftarrow PG + 1$ (carry occurred) $PG \leftarrow PG - 1$ (borrow occurred)	Jumps to the address indicated by the program counter plus the offset value.																															
BRK	$PC \leftarrow PC + 2$ $M(S) \leftarrow PG$ $S \leftarrow S - 1$ $M(S) \leftarrow PC_H$ $S \leftarrow S - 1$ $M(S) \leftarrow PC_L$ $S \leftarrow S - 1$ $M(S) \leftarrow PS_H$ $S \leftarrow S - 1$ $M(S) \leftarrow PS_L$ $S \leftarrow S - 1$ $I \leftarrow 1$ $PC_L \leftarrow AD_L$ $PC_H \leftarrow AD_H$ $PG \leftarrow 00_{16}$	Executes software interruption.	00	15	2																												
BVC (Note 3)	$V=0?$	Branches when the contents of the V flag is "0".																															
BVS (Note 3)	$V=1?$	Branches when the contents of the V flag is "1".																															
CLB (Note 5)	$Mb \leftarrow 0$	Makes the contents of the specified bit in the memory "0".																14	8	3													
CLC	$C \leftarrow 0$	Makes the contents of the C flag "0".	18	2	1																												
CLI	$I \leftarrow 0$	Makes the contents of the I flag "0".	58	2	1																												
CLM	$m \leftarrow 0$	Makes the contents of the m flag "0".	D8	2	1

CPY (Note 2)	Y←M	Compares the contents of the index register Y with the contents of the memory.				C0	2	2				C4	4	2																		
DEC (Note 1)	Acc←Acc-1 or M←M-1	Decrements the contents of the accumulator or memory by 1.							1A	2	1	C6	7	2				D6	7	2												
									42	4	2																					
									1A																							
DEX	X←X-1	Decrements the contents of the index register X by 1.	CA	2	1																											
DEY	Y←Y-1	Decrements the contents of the index register Y by 1.	B8	2	1																											
DIV (Note 2,10)	A(quotient)←B,A/M B(remainder)	The numeral that places the contents of accumulator B to the higher order and the contents of accumulator A to the lower order is divided by the contents of the memory. The quotient is entered into accumulator A and the remainder into accumulator B.				89	27	3				89	29	3				89	30	3				89	31	3	89	32	3	89	33	3
						29						25						35						32			21			31		
DIVS* (Note 2,14)	A(quotient)←B,A/M B(remainder) with sign	The numeral with sign that places the contents of accumulator B to the higher order and the contents of accumulator A to the lower order is divided by the contents of the memory. The quotient is entered into accumulator A and the remainder into accumulator B.				89	29	3				89	31	3				89	32	3				89	33	3	89	34	3	89	35	3
						A9						A5						B5						B2			A1			B1		
EOR (Note 1,2)	Acc←AccVM	Logical exclusive sum is obtained of the contents of the accumulator and the contents of the memory. The result is placed into the accumulator.				49	2	2				45	4	2				55	5	2				52	6	2	41	7	2	51	8	2
						42	4	3				42	6	3				42	7	3				42	8	3	42	9	3	42	10	3
						49						45						55						52			41			51		
EXTS* (Note 1)	Bit 7 of Acc=1 b15 b7 11111111 1 Bit 7 of Acc=0 b15 b7 00000000 0	The signed 8-bit data stored in the low-order byte of the accumulator is extended to a 16-bit data.				89	8	2																								
						8B																										
						42	8	2																								
						8B																										
EXTZ* (Note 1)	Acc b15 b8 b7 b0 00000000	The 8-bit data stored in the low-order byte of the accumulator is extended to a 16-bit data. Bits 8 to 15 of the accumulator are set to "0".				89	5	2																								
						AB																										
						42	5	2																								
						AB																										
INC (Note 1)	Acc←Acc+1 or M←M+1	Increments the contents of the accumulator or memory by 1.				3A	2	1	E6	7	2							F6	7	2												
						42	4	2																								
						3A																										
INX	X←X+1	Increments the contents of the index register X by 1.	E8	2	1																											
INY	Y←Y+1	Increments the contents of the index register Y by 1.	C8	2	1																											
JMP	ABS PC _L ←AD _L PC _H ←AD _H ABL PC _L ←AD _L PC _H ←AD _H PG←AD _G (ABS) PC _L ←(AD _H , AD _L) PC _H ←(AD _H , AD _L +1) L(ABS) PC _L ←(AD _H , AD _L) PC _H ←(AD _H , AD _L +1) PG←(AD _H , AD _L +2) (ABS, X) PC _L ←(AD _H , AD _L +X) PC _H ←(AD _H , AD _L +X+1)	Places a new address into the program counter and jumps to that new address.																														

APPENDIX.1 Machine Instructions

[illegible]

APPENDIX

APPENDIX.1 Machine Instructions

Symbol	Function	Details	Addressing mode																														
			IMP			IMM			A			DIR			DIR.b			DIR.X			DIR.Y			(DIR)			(DIR.X)			(DIR.Y)			
			op	n	#	op	n	#	op	n	#	op	n	#	op	n	#	op	n	#	op	n	#	op	n	#	op	n	#	op	n	#	
JSR	ABS M(S) ← PC _H S ← S-1 M(S) ← PC _L S ← S-1 PC _L ← AD _L PC _H ← AD _H ABL M(S) ← PG S ← S-1 M(S) ← PC _H S ← S-1 M(S) ← PC _L S ← S-1 PC _L ← AD _L PC _H ← AD _H PG ← AD _B (ABS, X) M(S) ← PC _H S ← S-1 M(S) ← PC _L S ← S-1 PC _L ← (AD _H , AD _L +X) PC _H ← (AD _H , AD _L +X+1)	Saves the contents of the program counter (also the contents of the program bank register for ABL) into the stack, and jumps to the new address.																															
LDA (Note 1,2)	Acc ← M	Enters the contents of the memory into the accumulator.				A9	2	2				A5	4	2				B5	5	2				B2	6	2	A1	7	2	B1	8	2	
						42	4	3				42	6	3				42	7	3				42	8	3	42	9	3	42	10	3	
						A3						A5						B5						B2			A1			B1			
LDM (Note 5)	M ← IMM	Enters the immediate value into the memory.										64	4	3				74	5	3													
LDT	DT ← IMM	Enters the immediate value into the data bank register.				89	5	3																									
						C2																											
LDX (Note 2)	X ← M	Enters the contents of the memory into index register X.				A2	2	2				A6	4	2					B5	5	2												
LDY (Note 2)	Y ← M	Enters the contents of the memory into index register Y.				A0	2	2				A4	4	2					B4	5	2												
LSR (Note 1)	m=0 0 → [b ₁₅ ...b ₀] → C m=1 0 → [b ₇ ...b ₀] → C	Shifts the contents of the accumulator or the contents of the memory one bit to the right. The bit 0 of the accumulator or the memory is entered into the C flag. "0" is entered into bit 15 (bit 7 when the m flag is "1".)							4A	2	1	46	7	2				56	7	2													
									42	4	2																						
						4A																											
MPY (Note 2,11)	B, A ← A * M	Multiplies the contents of accumulator A and the contents of the memory. The higher order of the result of operation are entered into accumulator B, and the lower order into accumulator A.				89	16	3				89	18	3				89	19	3				89	20	3	89	21	3	89	22	3	
						09						05						15						12			01			11			
MPYS* (Note 2,15)	B, A ← A * M with sign	The content of the accumulator A is multiplied by the content of memory as signed data. The result is a 32-bit data which is placed in the accumulators B (upper 16 bits of the result) and A (lower 16 bits of the result).				89	18	3				89	20	3				89	21	3				89	22	3	89	23	3	89	24	3	
						89						85						95						92			81			91			
MVN (Note 8)	M _n +i ← M _m +i	Transmits the data block. The transmission is done from the lower order address of the block.																															
MVP (Note 9)	M _n -i ← M _m -i	Transmits the data block. Transmission is done from the higher order address of the data block.																															
NOP	PC ← PC+1	Advances the program counter, but performs nothing else.	EA	2	1																												
ORA (Note 1,2)	Acc ← Acc ∨ M	Logical sum per bit of the contents of the accumulator and the contents of the memory is obtained. The result is entered into the accumulator.				09	2	2				05	4	2				15	5	2				12	6	2	01	7	2	11	8	2

APPENDIX.1 Machine Instructions

EOL announced

APPENDIX

APPENDIX.1 Machine Instructions

The number of cycles shown in the table is described in case of the fastest mode for each instruction. The number of cycles shown in the table is calculated for $DPR_L=0$. The number of cycles in the addressing mode concerning the DPR when $DPR_L \neq 0$ must be incremented by 1. The number of cycles shown in the table differs according to the bytes fetched into the instruction queue buffer, or according to whether the memory read/write address is odd or even. It also differs when the external region memory is accessed by $BYTE="H"$.

Note 1. The operation code at the upper row is used for accumulator A, and the operation at the lower row is used for accumulator B.

Note 2. When setting flag $m=0$ to handle the data as 16-bit data in the immediate addressing mode, the number of bytes increments by 1.

Note 3. The number of cycles increments by 2 when branching.

Note 4. The operation code on the upper row is used for branching in the range of $-128 \sim +127$, and the operation code on the lower row is used for branching in the range of $-32768 \sim +32767$.

Note 5. When handling 16-bit data with flag $m=0$, the byte in the table is incremented by 1.

Note 6.

Type of register	A	B	X	Y	DPR	DT	PG	PS
Number of cycles	2	2	2	2	2	1	1	2

The number of cycles corresponding to the register to be pushed are added. The number of cycles when no pushing is done is 12. i_1 indicates the number of registers among A, B, X, Y, DPR, and PS to be saved, while i_2 indicates the number of registers among DT and PG to be saved.

Note 7.

Type of register	A	B	X	Y	DPR	DT	PS
Number of cycles	3	3	3	3	4	3	3

The number of cycles corresponding to the register to be pulled are added. The number of cycles when no pulling is done is 14. i_1 indicates the number of registers among A, B, X, Y, DT, and PS to be restored, while $i_2=1$ when DPR is to be restored.

Note 8. The number of cycles is the case when the number of bytes to be transferred is even.

When the number of bytes to be transferred is odd, the number is calculated as;

$$7 + (i/2) \times 7 + 4$$

Note that, $(i/2)$ shows the integer part when i is divided by 2.

Note 9. The number of cycles is the case when the number of bytes to be transferred is even.

When the number of bytes to be transferred is odd, the number is calculated as;

$$9 + (i/2) \times 7 + 5$$

Note that, $(i/2)$ shows the integer part when i is divided by 2.

Note 10. The number of cycles is the case in the 16-bit \div 8-bit operation. The number of cycles is incremented by 16 for 32-bit \div 16-bit operation.

Note 11. The number of cycles is the case in the 8-bit \times 8-bit operation. The number of cycles is incremented by 8 for 16-bit \times 16-bit operation.

Note 12. When setting flag $x=0$ to handle the data as 16-bit data in the immediate addressing mode, the number of bytes increments by 1.

Note 13. When flag m is 0, the byte in the table is incremented by 1.

Note 14. The cycles-count in this table are for 8-bit \times 8-bit multiplications with the same sign. If the multiplier and multiplicand have different signs, three additional cycles are required. For 16-bit \times 16-bit multiplications, the cycles-count increases by 8.

Note 15. The cycles-count in this table are for 16-bit \div 8-bit operations. For 32-bit \div 16-bit operations, the cycles-count increases by 16.

APPENDIX

APPENDIX.1 Machine Instructions

Symbols in machine instructions table

Symbol	Description	Symbol	Description
IMP	Implied addressing mode	↘	Exclusive OR
IMM	Immediate addressing mode	—	Negation
A	Accumulator addressing mode	←	Movement to the arrow direction
DIR	Direct addressing mode	A _{CC}	Accumulator
DIR, b	Direct bit addressing mode	A _{COH}	Accumulator's upper 8 bits
DIR, X	Direct indexed X addressing mode	A _{COL}	Accumulator's lower 8 bits
DIR, Y	Direct indexed Y addressing mode	A	Accumulator A
(DIR)	Direct indirect addressing mode	A _H	Accumulator A's upper 8 bits
(DIR, X)	Direct indexed X indirect addressing mode	A _L	Accumulator A's lower 8 bits
(DIR), Y	Direct indirect indexed Y addressing mode	B	Accumulator B
L (DIR)	Direct indirect long addressing mode	B _H	Accumulator B's upper 8 bits
L (DIR), Y	Direct indirect long indexed Y addressing mode	B _L	Accumulator B's lower 8 bits
ABS	Absolute addressing mode	X	Index register X
ABS, b	Absolute bit addressing mode	X _H	Index register X's upper 8 bits
ABS, X	Absolute indexed X addressing mode	X _L	Index register X's lower 8 bits
ABS, Y	Absolute indexed Y addressing mode	Y	Index register Y
ABL	Absolute long addressing mode	Y _H	Index register Y's upper 8 bits
ABL, X	Absolute long indexed X addressing mode	Y _L	Index register Y's lower 8 bits
(ABS)	Absolute indirect addressing mode	S	Stack pointer
L (ABS)	Absolute indirect long addressing mode	PC	Program counter
(ABS, X)	Absolute indexed X indirect addressing mode	PC _H	Program counter's upper 8 bits
STK	Stack addressing mode	PC _L	Program counter's lower 8 bits
REL	Relative addressing mode	PG	Program bank register
DIR, b, REL	Direct bit relative addressing mode	DT	Data bank register
ABS, b, REL	Absolute bit relative addressing mode	DPR	Direct page register
SR	Stack pointer relative addressing mode	DPR _H	Direct page register's upper 8 bits
(SR), Y	Stack pointer relative indirect indexed Y addressing mode	DPR _L	Direct page register's lower 8 bits
BLK	Block transfer addressing mode	PS	Processor status register
C	Carry flag	PS _H	Processor status register's upper 8 bits
Z	Zero flag	PS _L	Processor status register's lower 8 bits
I	Interrupt disable flag	PS _b	Processor status register's b-th bit
D	Decimal operation mode flag	M(S)	Contents of memory at address indicated by stack pointer
x	Index register length selection flag	M _b	b-th memory location
m	Data length selection flag	AD _G	Value of 24-bit address's upper 8-bit (A ₂₃ ~A ₁₆)
V	Overflow flag	AD _H	Value of 24-bit address's middle 8-bit (A ₁₅ ~A ₈)
N	Negative flag	AD _L	Value of 24-bit address's lower 8-bit (A ₇ ~A ₀)
IPL	Processor interrupt priority level	op	Operation code
+	Addition	n	Number of cycle
—	Subtraction	#	Number of byte
*	Multiplication	i	Number of transfer byte or rotation
/	Division	i ₁ , i ₂	Number of registers pushed or pulled
^	Logical AND		
∨	Logical OR

APPENDIX

APPENDIX.2 Hexadecimal Instruction Code Table

INSTRUCTION CODE TABLE - 3 (The first word's code of each instruction is 8916)

D7—D4	D3—D0 Hexadecimal notation	0000	0001	0010	0011	0100	0101	0110	0111	1000	1001	1010	1011	1100	1101	1110	1111
		0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
0000	0		MPY (DIR,X)		MPY SR		MPY DIR		MPY L(DIR)		MPY IMM				MPY ABS		MPY ABL
0001	1		MPY (DIR),Y	MPY (DIR)	MPY (SR),Y		MPY DIR,X		MPY L(DIR),Y		MPY ABS,Y				MPY ABS,X		MPY ABL,X
0010	2		DIV (DIR),X		DIV SR		DIV DIR		DIV L(DIR)	XAB	DIV IMM				DIV ABS		DIV ABL
0011	3		DIV (DIR),Y	DIV (DIR)	DIV (SR),Y		DIV DIR,X		DIV L(DIR),Y		DIV ABS,Y				DIV ABS,X		DIV ABL,X
0100	4										RLA IMM						
0101	5																
0110	6																
0111	7																
1000	8		MPYS* (DIR,X)		MPYS* SR		MPYS* DIR		MPYS* L(DIR)		MPYS* IMM		EXTS* A		MPYS* ABS		MPYS* ABL
1001	9		MPYS* (DIR),Y	MPYS* (DIR)	MPYS* (SR),Y		MPYS* DIR,X		MPYS* L(DIR),Y		MPYS* ABS,Y				MPYS* ABS,X		MPYS* ABL,X
1010	A		DIVS* (DIR),X		DIVS* SR		DIVS* DIR		DIVS* L(DIR)		DIVS* IMM		EXTZ* A		DIVS* ABS		DIVS* ABL
1011	B		DIVS* (DIR),Y	DIVS* (DIR)	DIVS* (SR),Y		DIVS* DIR,X		DIVS* L(DIR),Y		DIVS* ABS,Y				DIVS* ABS,X		DIVS* ABL,X
1100	C			LDT IMM													
1101	D																
1110	E																
1111	F																

Note 1. The code of each instruction first word is 8916.

Note 2. "*" shows the instructions can be used in 7750 Series.
